Advanced Model of Complex Information System

Miroslav Svitek

Czech Technical University in Prague, Czech Republic

INTRODUCTION

The proposed methodology represents the new ideas that come from defined mathematical assumptions like information-electrical or information-mechanical analogies. From these simple assumptions a lot of information physical principles can be derived like for example information flow, information content, information power, etc.

Analogies among electrical, mechanical and information circuits seem to be efficient attempts for problems solving within *systems engineering* by Vlček (1999). Concepts of *information power* and significant proximity of the measure of information and knowledge could enable upgrading these analogies for solving even wider class of tasks.

BACKGROUND

Data mean a change of state, for example from 0 to 1 or from 1 to 0, where the state vector is not necessarily only digital or one-dimensional. Every such change can be described with the use of a quantity of *information* in bits.

Information theory was founded by Shannon (1948) and his colleagues in the 1940s and was associated with coding and data transmission, especially in the newly emerging field of radar systems, which became a component of defensive systems during the Second World War.

Syntactic (Shannon) information has been defined as the degree of probability of a given event and has replied to the question: how often

a message appears? For example, by telling you that the solar system would cease to exist tomorrow, I would be giving you the maximum information possible, because the probability of this phenomenon occurring is nearly equal to zero. The probability model of information so defined has been used for the designing of self-repairing codes, digital modulations and other technical applications. Telecommunications specialists and radio engineers were concentrating on a probabilistic description of encoded data and on the minimizing of probability errors during data transmission.

The model-theoretical work of *semantic information* was done by Carnap and Bar-Hiller (1953). On the other hand, semantic information asks: how often a message is true? Zadeh (1965) introduced the theory of *fuzzy sets* as functions that map a value, which might be a member of a set, to a number between zero and one, indicating its actual degree of membership.

Currently, a number of interesting results have been discovered in the field of *quantum information science*, taking as their basis the foundations of quantum physics and using for modeling of complex systems those principles that do not arise in classical physics, such as *entanglement* and *quantization*. In the technical literature, we read that the behavior of entangled states is very odd. Firstly, it spreads rapidly among various phenomena, where for this spreading it makes use of a property known as *entanglement swapping*. The quantum information quantity in bits can be measured e.g. by *von Neumann entropy* in Vedral (2006) which measures the amount of uncertainty contained within the density operator taking into

account also wave probabilistic features like entanglement, quantization or bosonic / fermionic quantum behavior by Svítek (2012).

On the basis of the information theories, a number of methods and algorithms have emerged that attempt to eliminate or minimize indefiniteness and to do a better job of extracting the real, useful information from data. An excellent example is the *Bayes method* by Peterka (1981), which interprets the density of probability not as a description of a random quantity, but rather as a description of the indefiniteness of the system, i.e. how much information we have available about the monitored system. The system itself might be completely deterministic (describable without probability theory), but we may have very little available information about the system. When performing continuous measurement, we obtain more and more data, and therefore more information as well about our system, and our system begins to appear to us to be more definite. The elimination of indefiniteness therefore increases the quantity of information we have about the monitored system.

When eliminating indefiniteness, we also have to bear in mind the possibility of a change to the context of the event or phenomenon. There is plenty of testimony available to us from live witnesses, but there is none from dead ones, and this gives us an asymmetrical set of observations by Taleb (2010). It brings to mind the well-known saying that history is not written by the losers.

Once indefiniteness has been eliminated, one may proceed to the *interpretation of information*, or in other words, to the determination of how to reconstruct the described system, or how to build a more or less perfect model of it using the information. This task already belongs to the theory of systems, where it is necessary to identify the state vector, individual processes of the system etc. There emerges from this a knowledge system, which is able to describe the given object appropriately.

Information systems in Kelly and Cegielski (2009) aim to support management, operation and decision making, e.g. expert system, geographical

information system, enterprise system, etc. Components of computer-based information systems are hardware, software, databases, networks and procedures.

INFORMATION PHYSICS

Information behavior in Fidher, Erdelez and McKechnie (2005) means human behavior in relation to sources and channels of information - both active and passive information-seeking and use in different contexts. Information can be treated as physical matter or physical entity, and as such can be studied using the same methods as those applied by physics to study the properties of the physical matter. That is why new field *information physics* is established.

If we wish to apply information theory to the natural sciences, we should begin by describing information systems using a mathematical tool similar to one by which physics is described. We would therefore use analogies between various physical systems. In every such system, there exists potential and kinetic energy, to which there are corresponding quantities of potential and flow. In electronics, for example, voltage is defined as the quantity of potential, and electric current is the quantity of flow.

Let us then introduce a unit for the current of information and call it *information flow*, which is measured in bits per second and describes the input or output of information per unit of time. We can analogously define a quantity of potential, which we would call *information content*, which determines the quantity of work per bit (in Joules per bit). Information content for information systems (IT/ICT) can be defined as the number of 'success events' in the system per bit of information, and one may expect that if received information is significant, in information system a sequence of 'success events' is activated that orders our system. This also means that in order for us to obtain any concrete information content, we would already have to have done work, such as studying, searching for documentation, preparation etc. On the other

hand, it could be the other way around: the given information content might enable us to obtain a certain quantity of energy or (nowadays) funding.

From knowledge of information flow and information content, one can define other information physics quantities. One of the important quantities can be *information power*, defined by Svítek, Votruba and Moos (2010) as the product of information flow times information content. Analysis easily reveals that the unit of information power is work per second realized thanks to the received bit of information. For information systems (IT/ICT), information power is defined as the number of “success events” per second caused by the receipt of one bit of information. By introducing the quantity of information power, one can demonstrate that the impact of information is maximized if the received information flow is appropriately processed by the recipient and transformed into the best possible information content. If there is a flow of valuable information that the recipient is incapable of processing, the information power level is low. On the other hand, if the recipient is able to make good use of the information flow, but the flow does not carry needed information, the result is likewise a low level of information power.

We can take these ideas even further and introduce a phase shift between the information flow and content, thereby arriving at the definition of active and reactive information power by Svítek (2011). We can imagine *active information power* as power caused by information, which is transformed directly into concrete physical events. *Reactive information power* represents our emotions, which of course do not perform any work, but which support our decision making. Worth mentioning in this context is a well-known Bible story: King Solomon proposes to have a child split in half when two women are fighting over it, but because of her emotions, the real mother would rather give up her child than let it be killed.

An interesting area of information physics is the perception of time, which we can imagine as the number of biological events taking place in our bodies with a given frequency. If the information

power intake is slower than our biological clocks, we have the feeling that time is moving slowly, but if intake is faster, we have the feeling that time is being well used.

INFORMATION: PHYSICAL ANALOGIES

In Svítek, Votruba, Moos (2010) the extended Frege’s information concept was presented based on result of Vlček (1999). In Figure 1 basic information quantities are given:

$O_i(t)$ - a set of rated quantities on an object,

$P_i(t)$ - a set of states,

$\Phi_i(t)$ - a set of syntactic strings (data flow),

$I_i(t)$ - a set of information images of state quantities.

In physics, the state is a complete description of a system in terms of parameters at a particular moment in time. Thermodynamic state is a set of

Figure 1. Frege’s functional concept of information image origin and action

physical quantities (e.g. temperature, pressure, and composition) describing variable properties.

Other parameters representing links between information quantities are as follows:

a_{op} – identification,

a_{po} – invasivity,

$a_{p\phi}$ – projection in a set of symbols and syntactical strings,

$a_{\phi p}$ – uncertainty correction and identification,

$a_{\phi i}$ – interpretation, information origin,

$a_{i\phi}$ – language constructs reflection,

a_{io} – relation of functions and structural regularity,

a_{oi} – integrity verification.

The circuit theoretician Chua (1971) introduced the basic concept of electrical components together with the relations between them as it is shown in Figure 2. There are six different math-

ematical relations connecting pairs of the four fundamental circuit variables:

$q(t)$ - charge,

$\phi(t)$ - magnetic flux,

$i(t)$ - electric current,

$v(t)$ - voltage.

From electrical variables definition we know that the charge is the time integral of the current. Faraday's law tells us that the flux is the time integral of the electromotive force, or voltage. There should be four basic circuit elements described by relations between variables: resistor, inductor, capacitor and memristor. Chua's concept is famous due to an envisioned new electrical component named "memristor" that provides a functional relation between charge $q(t)$ and flux $\phi(t)$.

Let us use the analogies between Chua's electrical and Frege's information concepts. Electrical charge $q(t)$ is measured in coulombs [c] and can be understood as basic electrical unit in analogy with the information unit measured in bits [bit]. Quantum physics really defines the quantum information unit called q-bit. We speak of (input / output) data changes $O_i(t)$ through which the system's model can be estimated.

Magnetic flux $\phi(t)$ is naturally related to the system states $P_i(t)$ which should be viewed as the piece of extracted knowledge (e.g. parameters estimated based on the observed data, understanding why system behaves in such a way, etc.). Time evolution of system states characterizes the system behavior. Magnetic flux is measured in webers [wb] corresponding to Joule multiplied by second and divided by coulomb [J.s/c]. In agreement with our analogy the states $P_i(t)$ are measured in [J.s/bit] which notes how much energy can be ex-

Figure 2. Chua's concept of electrical quantities

tracted / delivered based on one bit of information within one second.

Electrical current $i(t)$ measured in coulomb per second [c/s] is related to the information (syntax) flow $\Phi_i(t)$ that describes dynamical property of data changes in bits per second [bit/s]. The information flow $\Phi_i(t)$ typically represents the system input / output data flows per time.

Electrical voltage $v(t)$ leads to the analogical definition of the information (semantic) content $I_i(t)$ which characterizes the knowledge content measured in Joule per bit [J/bit]. For information systems (IT/ICT), the information content in [J/bit] can be alternatively defined as the number of “success events” caused by the receipt of one bit of information.

COMPLEX INFORMATION SYSTEMS

On the basis of the previous definitions, we can continue with the quantities we have introduced, information flow and information content, as well as with the quantities we have derived from them, such as information power. For the sake of simplicity, let us imagine an information subsystem as an *input-output information gate* given on Figure 3.

Between the input ports, input information content is available, and input information flow enters the system. Between the output ports, it is possible to obtain output information content, and output information flow leaves the system.

We can furthermore assume that this subsystem is open and is capable of using its surroundings as a source for drawing energy. Kauffman (2004) introduced the term *autonomous living agents*, which are characterized by the ability to direct and release energy. Kauffman is also the originator of the idea that the orderliness that is characteristic of living systems is defined by a series of actions leading to the dissemination of macroscopic work.

Figure 3. Information gate (Φ - information flow of data measured in bits per second, I - information content measured in Joule per bits)

Let us now examine the input-output information gate we have created. Input quantities can describe purely intellectual operations. Input information content includes our existing knowledge, and input information flow describes the change to the environment in which our gate operates and the tasks we want carried out (target behavior). All of the valuable, long-term information gained in this way can be used for the targeted release of energy, where at the output of the input-output gate, there may be information content on the order of millions of Joules per bit (or profits in millions of dollars). The output information flow serves as a model of the providing of such services or knowledge.

The basis of information systems is the ability to interconnect individual information subsystems, or in our case, input-output information gates. It is very easy to imagine the serial or parallel ordering of these subsystems into higher units. A very interesting model is feedback of information subsystems, because it leads to non-linear characteristics, to information systems defined at the limit of stability and other interesting properties. In this manner one may define *information filters*,

which are able to select, remove or strengthen a particular component of information.

FUTURE RESEARCH DIRECTIONS: POSSIBLE EXAMPLE

In the context of information physics, it is also necessary to deal with the problem of teaching, because the information subsystem called a *teacher* may be regarded as a source of information content. The teacher has prepared this information content for years with respect to both the content as such (optimizing the information content) and its didactic presentation (optimizing the information flow), so that the knowledge can be passed on to a subsystem known as a *student*. If we assume that the teacher subsystem has greater information content than the student subsystem, after their interconnection, the information flow will lead from the teacher to the student, so that the information content of the two subsystems will gradually balance out.

The students receive the information flow and increase their information content. If the students are not in a good mood, or if the information flow from the teacher is confused, the students are unable to understand the information received and to process it, so as to increase their information content. With the help of the reactive information power mentioned above, which concerns the emotional aspects of the recipient and the source, i.e. the student and the teacher, it is possible to create a situation where the students' sensitivity to the received information flow is maximized, so that they are able to process it appropriately and transform it into information content. Analogously, the teacher being in a good mood can lead to the creation of better information flow.

The individual components and subsystems of information systems can behave in different ways, and their behavior can be compared to everyday situations in our lives. A characteristic of politicians is their ability to use even a small input of information content to create a large output infor-

mation flow. They have the ability to take a small amount of superficially understood content and to interpret and explain it to the broadest masses of people. On the other hand, a typical professor might spend years receiving input information flow and input information content, and within her/his field, he/she may serve as a medium for transmitting a large quantity of output information content. The professor, however, might not spread the content very far, sharing it perhaps only with a handful of enthusiastic students.

It is hard to find an appropriate system to combine the characteristics of the different information subsystems described above, but it is possible to create a group of subsystems - system alliances introduced by Votruba and Novák (2010), where these characteristics can be combined appropriately. In this way, one can model a company or a society of people who together create information output that is very effective and varied, leading to improved chances for the survival and subsequent evolution of the given group. Such approach yields into *society knowledge* firstly introduced by Hayek (1945).

Through an appropriate combination of its internal properties, our information alliance can react and adapt to the changing conditions of its surroundings. Survival in alliances thus defined seems more logical and natural than trying for a combination of all necessary processes within the framework of one universal information subsystem.

CONCLUSION

For many years, I have been observing how much difficulty natural sciences have with explaining the basis of life, the behavior of living beings or of society, and how such important terms as *information* or *knowledge* have gradually crept into thinking in these fields.

It is as if we were building a house. We would need material (or mass), we would need plenty of workers (or energy), but without knowledge of

the plans for when and how to build, we could not erect the house. Information and knowledge are therefore the things that could enrich the natural sciences, enabling them to describe more faithfully the world around us.

In this text I tried to present basic approach to the information physics and to the complex information systems. I personally believe that the capturing of processes in the world around us with the help of information and knowledge subsystems organized into various interconnections, especially with feedback, can lead to the controlled dissemination of macroscopic work as described by Kauffman (2004), and after the overcoming of certain difficulties, even to the description of the behavior of living organisms.

I am convinced that the future will see a convergence of the physical sciences, life sciences and engineering. I would even allow myself to go a bit further, to consider even convergence with the humanities, because I am convinced that the laws of behavior of human society described, for example, in sociology or political science will be able to be better understood using the tools of information physics.

From the examples given above, I see the possibility for linking the physical world with the world of information, because every information flow must have its transmission medium, which is typically a physical object (e.g. physical particles) or a certain property of such an object. The case is again similar with information content, which also must be encoded through a real, physical system. The operations defined above the information systems can then likewise be depicted in a concrete physical environment.

Presented ideas may be controversial though in the information science field, as it continues the debate as to whether information can be treated as a thing or physical entity or whether it is socially constructed and does not exist outside of the human mind as was defined by Penrose (1989). This chapter should at least acknowledge that debate.

KEY TERMS AND DEFINITIONS

Fuzzy Information: Determines the actual degree of set membership (fuzzy set) to a number between zero and one.

Information Content: Determines the quantity of work per bit and it is measured in Joules per bit.

Information Flow: Describes the input or output of information per unit of time and it is measured in bits per second.

Information Power: Determines the product of information flow and information content and it is measured in Joules per second.

Quantum Information: Determines how to integrate information theory with quantum mechanics, by studying how information can be stored with and retrieved from a quantum mechanical system. The primary piece of information in quantum information theory is the qubit, an analog to the bit (0 or 1) in classical information theory.

Semantic Information: Describes the content level of a given event and replies to the question: how often a message is true?

Shannon Entropy: Is a measure of the uncertainty in a random variable and quantifies the expected value of the information (in bits) contained in a message.

Syntactic Information: Describes the degree of probability of a given event and replies to the question: how often a message appears?

Von Neumann Entropy: Is the extension of Shannon entropy to the field of quantum mechanical systems described by a density matrix.

Computer Information Library Clusters

Fu Yuhua

CNOOC Research Institute, China

INTRODUCTION

As well-known, the concept of “set” has been constantly expanded and developed. For example, it can be expanded and developed into the concepts of “generalized set” and the like. At present, many theories and practices demonstrate the viability of big data analysis as a global business activity. In order to meet the needs of big data analysis and the like, we consider that the concepts of “generalized set” and the like should be expanded and developed into the concept of “computer information library clusters” (CILC).

DEFINITIONS AND NOTATIONS

In this section we shall present some basic definitions and notations.

Definition 1: The expanded and developed result of set is defined as generalized and hybrid set.

Definition 2: The expanded and developed result of generalized and hybrid set is defined as library.

Definition 3: The expanded and developed result of libraries related to computer information is defined as “computer information library clusters” (CILC).

Definition 4: In this paper, the variation principle is defined as the following standard form

$$\Pi = \min_0$$

where: $\min_0$ is the minimum and its value should be equal to zero.

More definitions and notations can be found in (Fu, 2013), (Fu, 2016a), and (Fu, 2016b) respectively.

BACKGROUND

In (Fu, 2016a), generalized and hybrid set can be created with neutrosophy and quad-stage method. In which, generalized and hybrid set are discussed firstly; based on this, the concepts of “problem set”, “solution set”, “principle set”, “law set”, “theory set”, “formula set”, and the like are presented; Secondly the combination or synthetic body of generalized and hybrid sets is named as “library” (various generalized and hybrid sets can be put into the related “library”); such as “mathematics library”, “physics library”, “natural science library”, “social science library”, and the like. As for the constitution of “library”, referring to quad-stage method and Chinese ancient “Complete Library of Four Branches of Books”, the concept and methodology of a special “Four-library” (including four sub-libraries: information library, question library, correlation library, and achievement library) are proposed. Neutrosophy and quad-stage method can also be used to solve many practical problems within the framework of “set” and “library”; for example, based on the analyses of one “Four-library”, jointly solving problem of advance of planet’s perihelion with partial results of law of gravity and general relativity (these two theories belong to “gravitational theory set”); and jointly expanding “uncertainty principle” to “certainty-uncertainty principle set” (including three principles in different conditions:

“certainty principle”, “uncertainty principle”, and neutral (fuzzy) “indeterminacy principle”) with Heisenberg inequality and Ozawa inequality. Finally, with the help of the concepts of “generalized and hybrid set” and “library”, we introduce the concepts of “variation principle of set” and “variation principle of library”, and establish a kind of “partial and temporary unified theory of mathematics so far”.

Based on the concept of “library” presented in (Fu, 2016a), this paper presents the concept of “computer information library clusters” (CILC).

CONSTITUTION OF “COMPUTER INFORMATION LIBRARY CLUSTERS” (CILC)

There are various ways and means to form CILC. For instance, CILC can be considered as the “total-library”, and consists of several “sub-libraries”. The example is the “Four-library” presented in (Fu, 2016a) (including four sub-libraries: information library, question library, correlation library, and achievement library). As another example, in CILC, a “total-library” can be set up, and a number of “sub-libraries” are side by side with the “total-library”. In which, the relationships between “total-library” and “sub-libraries” are also various. In (Fu, 2016a), the “total-library” may include all or part of the contents (such as directory, abstracts, etc) of sub-libraries. Of course, generally the “total-library” includes part of the contents of sub-libraries only.

EXAMPLES OF “COMPUTER INFORMATION LIBRARY CLUSTERS” (CILC)

For the sake of convenience, only discuss the situation that the “total-library” consists of a number of “sub-libraries”. In which, “sub-library” can be

divided into “first order sub-library”, “second order sub-library”, and the like.

Firstly, we discuss “natural science computer information library clusters”. If it is seen as the “total-library”, then the “sub-library” can be constituted in the following three ways: (1) constituted in accordance with discipline, (2) constituted in accordance with name, (3) constituted in accordance with A to Z sequence.

If constituted in accordance with discipline, the “first order sub-libraries” include: “mathematics library”, “physics library”, “chemistry library”, “biology library”, “medicine library”, and so on. In “mathematics library”, “second order sub-libraries” include: “algebra library”, “geometry library”, “trigonometry library”, “calculus library”, and so on.

If constituted in accordance with name, the “first order sub-libraries” include: “Newton library”, “Einstein library”, “Archimedes library”, “Euclid library”, “Qian Xuesen library”, and so on. In “Newton library”, “second order sub-libraries” include: “Newton mathematics library”, “Newton physics library”, “Newton mechanics library”, and so on.

If constituted in accordance with A to Z sequence, the “first order sub-libraries” include: “information library that begin with the letter A” to “information library that begin with the letter Z”. In “information library that begin with the letter A”, “second order sub-libraries” include: “information library that begin with the letters AA” to “information library that begin with the letters AZ”.

Secondly, the “computer information library clusters” (CILC) can also be constituted according to the different requirements and different points of interest. Specially, for CILC, the operation functions can be added.

For example, in (Fu, 2013), for unified dealing with the problems of natural science, applying least square method, “partial and temporary unified theory of natural science so far” can be

expressed in the following form of “partial and temporary unified variation principle of natural science so far”

$$\Pi_{\text{NATURE}} = \sum_1^n W_i \int_{\Omega_i} F_i^2 d\Omega_i + \sum_1^m W_j' S_j^2 = \min_0 \quad (1)$$

where: the subscript NATURE denotes that the suitable scope is all of the problems of natural science, all of the equations $F_i = 0$ denote so far discovered (derived) all of the equations related to natural science (their suitable scopes are Ω_i), all of the equations $S_j = 0$ denote so far discovered (derived) all of the solitary equations related to natural science (they are suitable on solitary points or in some special cases, the meanings can be found in (Fu, 2013)), W_i and W_j' are suitable positive weighted constants, and $\min_0$ was introduced in (Fu, 1989), indicating the minimum and its value should be equal to zero.

In this way, the theory of everything to express all of natural laws, described by Hawking that a single equation could be written on a T-shirt, is partially and temporarily realized in the form of “partial and temporary unified variation principle of natural science so far”.

However, the disadvantages of such a “partial and temporary unified theory of natural science so far” are also very obvious, namely it is disorganized and lack of layers.

In order to avoid these disadvantages, we introduce some concepts according to the thought of “computer information library clusters” (CILC).

The first one is the concept of “variation principle of library”.

The meaning of “variation principle of library” is the variation principle formed by using least square method (LSM) to process all equations and equalities included in the library.

By using least square method (LSM) to process the equations and equalities related to “library of quadratic equation of one unknown”, we have

the following “variation principle of library of quadratic equation of one unknown”

$$\Pi_{\text{QEOOlibrary}} = \Pi_1 + \Pi_2 + \Pi_3 + \dots = \min_0$$

where: the subscript QEOOlibrary denotes “library of quadratic equation of one unknown”, $\Pi_1 = F_1^2, \Pi_2 = F_2^2, \Pi_3 = F_3^2, \dots$

Similarly, for “library of cubic equation of one unknown”, we have “variation principle of library of cubic equation of one unknown” ($\Pi_{\text{CEOOlibrary}} = \min_0$); for “library of quartic equation of one unknown”, we have “variation principle of library of quartic equation of one unknown” ($\Pi_{\text{Q'EOOlibrary}} = \min_0$); and the like.

In addition, we expand the concepts of equation and solution, and discuss point equation, line equation, plane equation, solid equation, sub-domain equation, whole-domain equation, and the like; as well as point solution, line solution, plane solution, solid solution, sub-domain solution, whole-domain solution, and the like in (Fu, 2016b). Accordingly, the concepts of “point equation library”, “line equation library”, “plane equation library”, “solid equation library”, “sub-domain equation library”, “whole-domain equation library”, and the like; as well as “point solution library”, “line solution library”, “plane solution library”, “solid solution library”, “sub-domain solution library”, “whole-domain solution library”, and the like, can be presented. Furthermore, the related “variation principle of library” can be presented also.

For “natural science computer information library clusters” (natural science CILC), applying “variation principle of library”, “partial and temporary unified theory of natural science so far” with different degrees can be established as follows

$$\Pi_{\text{NATURElibrary}} = \Pi_{\text{MATHsublibrary}} + \Pi_{\text{PHYSsublibrary}} + \Pi_{\text{CHEMsublibrary}} + \dots = \min_0 \quad (2)$$

where: $\Pi_{\text{MATHsublibrary}}$ is “variation principle of mathematics library”, $\Pi_{\text{PHYSsublibrary}}$ is “variation principle of physics library”, $\Pi_{\text{CHEMsublibrary}}$ is “variation principle of chemistry library”.

For more applications of “variation principle of library”, referring to the examples in (Fu, 2016a) that solving problem of advance of planet’s perihelion with partial results of law of gravity and general relativity (now, these two theories belong to “gravitational theory library”); and jointly expanding “uncertainty principle” to “certainty-uncertainty principle library” (including three principles in different conditions: “certainty principle”, “uncertainty principle”, and neutral (fuzzy) “indeterminacy principle”) with Heisenberg inequality and Ozawa inequality (now, these two inequalities belong to “inequality library”).

At present, as running various big data analysis, we can put all data into CILC in advance, then, for a special analysis, choosing related equations and formulas and applying “variation principle of library”, thus we can find the optimum or suitable result.

FUTURE RESEARCH DIRECTIONS

Referring to the concept of “natural science CILC”, the concepts of “social science CILC”, “natural science and social science CILC”, and the like, can be presented.

Similarly, referring to the concept of “computer information library clusters”, the concepts of “computer and non-computer information library clusters”, “earth information library clusters”, “solar system information library clusters”, “Milky Way galaxy information library clusters”, “universe information library clusters”, and the like, can be presented.

CONCLUSION

This paper discusses the concept of “computer information library clusters”(CILC), as well as other concepts of “information library clusters”. The examples in this paper show that, with the operation function, “computer information library clusters”, as well as other “information library clusters”, will have a wide range of applications. At present, the theories and methods proposed in this paper can pave the way for many practical applications, such as big data analysis and the like.

KEY TERMS AND DEFINITIONS

Computer Information Library Clusters (CILC): The expanded and developed result of libraries related to computer information is defined as “computer information library clusters” (CILC). For example, CILC can be considered as the “total-library”, and consists of several “sub-libraries”. As another example, in CILC, a “total-library” can be set up, and a number of “sub-libraries” are side by side with the “total-library”.

Partial and Temporary Unified Variation Principle of Natural Science So Far and Partial and Temporary Unified Theory of Natural Science So Far: For unified dealing with the problems of natural science, applying least square method, “partial and temporary unified theory

of natural science so far” can be expressed in the form of “partial and temporary unified variation principle of natural science so far”. In this way, the theory of everything to express all of natural laws, described by Hawking that a single equation could be written on a T-shirt, is partially and temporarily realized in the form of “partial and temporary unified variation principle of natural science so far”.

Variation Principle of Library: The meaning of “variation principle of library” is the variation principle formed by using least square method (LSM) to process all equations and formulas included in the library. It can pave the way for many practical applications, such as big data analysis and the like.

The Impact of the Impact of Meta-Data Mining From the SoReCom “A.S. de Rosa” @-Library

INTRODUCTION

The Social Representations Theory was founded by Serge Moscovici in 1961, and after more than 50 years, the study of social representations, originally specifically European, is currently a multilingual, worldwide discipline with a substantial body of literature, involving leading scholars from social psychology and other social sciences (de Rosa, 2011, 2013a, 2013b, 2016b; Sammut, Andreouli, Gaskell, & Valsiner, 2015; Lo Monaco, Delouvée, & Rateaux, 2016). The field of Social Representations represents a unifying meta-theoretical perspective on the social construction of knowledge and its relation to socially situated practices. It has important applications for the public and private sectors, acting as a bridge among disciplines including psychology, social psychology, sociology, cultural studies with pragmatic approach to language, semiotics, socio-history, anthropology, and communication studies (also including multidisciplinary approaches from computer sciences and new technologies) with important implications for institutional and organizational contexts, culture and health practices, inter-group relations, ideology and politics, economics, the environment, etc. Interested in how scientific knowledge is transformed by lay

people and the media into common sense, it is also a supra-disciplinary field because it has activated a conversation among social, human and natural scientists in a wide range of internationally recognised research programmes. These concern public understanding of the sciences and discoveries in various fields, such as medicine, environmental studies, biology, informatics, economy, political science, etc., and the social representations of complex new multidisciplinary topics like biogenetic foods, medical innovation, globalisation and climate change, forms of interaction through new media, the risk society, immigration, minority groups, racism and multiculturalism, human rights, European integration and enlargement, etc. Consequently, this field is open to trans-disciplinary and multi-methodological research approaches (experimental and field work). The “objects” studied have a strong societal impact and important practical applications “within” and “for” society in the political, economic and social spheres.

The diffusion of the theory of social representations have been an object of analysis in the bibliometric domain in the light of the critical debate, which still animates the community of scientists, stimulating meta-reflexive discussion and view exchanges among the members of our

scientific community on the preferable publishing options and collaborative strategies in the current editorial and academic scenario (de Rosa, 2015a).

The objective of this chapter is to discuss the “*impact of the impact*” of the social representations theory in the bibliometric culture era, *even beyond the journal’s impact*. At this purpose we will present both:

- A selection of results on the dissemination of the theory across the continents based on data and meta-data concerning authors’ countries and institutional affiliations, comparing articles published in “*not indexed*” and “*indexed*” journals as derived from the two largest bibliometric databases (Isi-web of Science Thomson and Reuters and Scopus-Elsevier);
- And the *geo-mapping* of the wider scientific production in Social Representations.

BACKGROUND

Background question concerns what is the value of the scientific networking, training and documentation activities in the new academic scenario dominated by the bibliometric assessment culture and by the impact of the technology to the science production and sharing (data-driven science, big data, open data, open access, etc.).

The spirit that animates our interest in considering the “*impact of the impact*” is coherent with the main assumptions of the “*impact beyond the impact factor*” (Zupanc, 2014), and with the conclusions/recommendations of final assessment report of the Higher Education Founding Council for England, Wales and Northern Ireland (HE-FCE) (<http://www.hefce.ac.uk/pubs/rereports/Year/2015/metrictide/Title,104463,en.html>)

- There is considerable skepticism among researchers, universities, representative bodies and learned societies about the broader use of metrics in research assessment and management.

- Peer review, despite its flaws, continues to command widespread support as the primary basis for evaluating research outputs, proposals and individuals. However, a significant minority is enthusiastic about greater use of metrics, provided appropriate care is taken.
- Carefully selected indicators can complement decision-making, but a ‘variable geometry’ of expert judgement, quantitative indicators and qualitative measures that respect research diversity will be required.
- There is legitimate concern that some indicators can be misused or ‘gamed’: journal impact factors, university rankings and citation counts being three prominent examples.
- The data infrastructure that underpins the use of metrics and information about research remains fragmented, with insufficient interoperability between systems.
- Analysis concluded that no metric can currently provide a like-for-like replacement for REF peer review.
- In assessing research outputs in the REF, it is not currently feasible to assess research outputs or impacts in the REF using quantitative indicators alone.

and of the following 2015 report on “*Future approaches to quality assessment in England, Wales and Northern Ireland*”: <http://www.hefce.ac.uk/pubs/year/2015/201511/>.

More closely to our disciplinary field this spirit is coherent with the *opinion piece for the Bulletin of the European Association of Social Psychology*, written together with other internationally recognized social psychologists convened in a small meeting in Lausanne (June 12-14, 2013) to reflect on the new conformism dominating research practices in social psychology and to launch debate within the European Association of Social Psychology (EASP).

Another motivational driving force for involvement in the empirical investigation in the field of bibliometric culture is closely related to improve-

ment of the So.Re.Com. “A.S. de Rosa” @-library, and its exploitation as a scientific tool to conduct empirical research on the development and dissemination of the social representations literature around the world (by continents, countries, cities and even single institutions of author affiliation) and across the generations of scientists belonging to different academic cultures and contexts and working in different thematic areas, by different paradigmatic and methodological approaches. Adding the bibliometric indexes to the rich set of data and meta-data detected for each bibliographic item and filed in the bibliographic and meta-theoretical analysis repositories is intended to evaluate also the “*impact of the impact*” of the literature inspired by the social representations theory. Reconstructing the kind and evolution of inter-individual and inter-institutional co-operations is another goal of the wider meta-theoretical analysis research program. Further publications will be dedicated to the dynamics of the knowledge epidemiology via the inter-institutional collaborations between authors belonging to institutions in different countries and continents: *who* works with *whom*, (on what) and *where*?

GEO-MAPPING THE GLOBAL DISSEMINATION OF THE SOCIAL REPRESENTATIONS THEORY AND ITS IMPACT IN THE BIBLIOMETRIC CULTURE ERA

Coherently with the title of this chapter, our goal is to discuss some aspects of “*the IMPACT of the IMPACT*”, presenting a selection of results visualized according to a technique designed ad hoc (de Rosa, 2014b) for geo-mapping the development and the dissemination of the theory across the continents, over several generations of scientists, and according to thematic, paradigmatic and methodological approaches. Given the limited space available, here we will discuss only some of the comparative analyses based on “*big data*” and “*meta-data*” filed in our SoReCom “A.S. de Rosa” @-library repositories, concerning authors’

countries and institutional affiliations, years of publication by decades, thematic areas, language of publication, etc. and in particular:

1. Those related to the various bibliometric indexes (Impact Factor and SJR) as derived from the two largest bibliometric databases: Isi-web of Science Thomson and Reuters and Scopus-Elsevier, presenting the geo-mapping by Continents according to the country of the author’s institutional affiliation when considering comparatively the inclusion of the scientific production in both (a1.) or exclusively in just one of the two bibliometric databases of indexed journals (a.2);
2. The *geo-mapping* of the wider scientific production in Social Representations and comparative results with the restricted sources included in the indexed bibliometric databases;
3. The relevance of the crosscutting thematic choice for the articles in the top six “indexed journals”.

Sources for the Empirical Analyses and Main Results

We may define our data source as “big data” or almost “big data”, because up to now our SoReCom “A.S. de Rosa” @-library is the most comprehensive library specialised in Social Representation, compared the universe of the total literature. Although we are aware of classical definition of big data (see among others: Boyd & Crawford, 2012; Mayer-Schönberger & Cukier, 2013), we assume that “There is no one definition of Big Data. Thought about in simple terms, Big Data involves datasets that are far larger than those traditionally examined in journals like this one. Yet there has always been considerable variation in the size of datasets, ranging from small experimental studies to large samples involving census or polling data. Size alone is therefore an insufficient descriptor” (Parks, 2014: 255).

Figure 1. The distribution of 450 “indexed journals according to the inclusion in the bibliometric databases

The bibliographic sources of the empirical data used for our analyses were extracted from a larger number of 10325 bibliographic references (as of July 2015), of which 8740 items specifically related to social representations and communication (including also books, book chapters, conference presentations, web documents, manuscripts, university reports, Master and PhD theses, etc.) filed in the repositories of the *SoReCom “A.S. de Rosa” @-Library* (de Rosa, 2014a).

The results show that out of a total of 3239 articles:

- 1747 (54%) articles have been published in 624 “not indexed” journals
- 1492 (46%) in 450 “indexed” journals included in at least one of the bibliometric databases (Isi-web of Science Thomson and Reuters WoS and Scopus-Elsevier). The 450 journals are distributed as illustrated in the Figure 1 according to the criterion of inclusion in both or at least one of the two bibliometric databases: although the majority (65%, $f=295$) are indexed by both IF and SJR, those indexed only by IF (included in Isi-Web of Science) represent the 9% ($f=40$) compared to the 26% ($f=115$) indexed by SJR (included in Scopus-Elsevier).

This wide range of 450 “indexed” journals is in itself an indicator of the impact of the Social Representations theory and research field, which has gained its visibility beyond the borders of social psychology and, thanks to its supra-disciplinary epistemological power of attractiveness, has reached audience in journals from many disciplinary and thematic fields.

Based on a selection of 3239 articles related to Social Representations and Communication published in journals, the analyses of the results (Figure 2 and Figure 3) show that 1088 (34%) are included in both the databases from which the bibliometric indexes were extracted:

- *Impact Factor* (Thomson and Reuters) = 1174 articles, of which only 81 (2%) were included exclusively in Isi-web of Science;
- *SJR* (Scopus-Elsevier) = 1.414 articles, of which only 323 (10%) were included exclusively in Scopus.

Inspection of the frequencies distribution of indexed journals included in one or two bibliometric databases by journal’s “country ranking” clearly shows the dominance of English-speaking countries: United Kingdom (especially for the scientific production published in indexed journals by Scopus-Elsevier: SJR SCImago) for Europe

Figure 2. Sources: the distribution of 3239 articles published in 1074 “not indexed” and “indexed journals”

Figure 3. The distribution of 3239 articles published in “not indexed” journals or included in one or both of the “bibliometric databases”

as a continent and the United States (the only North American country appearing for the scientific production published in indexed journals by Isi-web of Science: IF), for the continent of America, followed by the Netherlands (a country where scientists publish mainly in English and are strongly linked with the British and North American scientific world and where the headquarters of the Elsevier publishing multinational company is located) (see Fig. 4).

Geo-Mapping the Wider Scientific Production in Social Representations and Comparative Results with the Restricted Sources Included in the Indexed Bibliometric Databases

Comparison of the results based on the indexed journals with the geo-mapping by the authors' institution continents based on all 3234¹ articles on

Figure 4. The frequencies distribution by “country ranking” based on the 450 “indexed journals” included in at least one or two bibliometric databases *Isi-Web of Science (IF)* and *Scopus (SJR SCImago)*

social representations published in journals filed in the *SoReCom “A.S. de Rosa” @-library* bibliographic repository (and not only in the 450 indexed journals by “country ranking” as represented in the Figure 8) evidences the prominence of Europe, and even more so of Latin America (compared to North America), for articles published in non indexed journals; whereas North America, Asia and Oceania are the prominent continents for articles published in indexed journals, compared to Europe (where the theory was initially generated and spread) and to Latin America (where the theory has been largely disseminated in the last two decades).

The next graphs – realised by the software *Tableau Desktop* (<http://www.tableausoftware.com>) – visualize the massive data based on the wider scientific production in Social Representations (on 3234 articles on social representations published in journals filed in the *SoReCom “A.S. de Rosa”*

@-library bibliographic repository) respectively on worldwide scale (Figure 5) with respective zooms on Continents and geo-cultural American Regions (Europe: Figure 6; Latin America: Figure 7; North America: Figure 8; Oceania: Figure 9; Asia: Figure 10; Africa: Figure 11). These graphs visualize on world wide scale the absolute frequencies for each country the distinction between the articles published in “non indexed journals”, those published in journal indexed in both or one of the bibliometric data bases (Thomson and Reuters for Impact Factor or Scopus-Elsevier for SJR). Therefore they clearly show – both on worldwide scale with a zoom on country by country in each continent - the comparative results based on the wider scientific production in the format of 3234 articles with the restricted sources included in one or both the indexed bibliometric databases, as already analytically described in the previous sections.

Figure 5. The absolute frequencies’ distribution of 3234 in articles (filed in the repositories of the SoReCom “A.S. de Rosa” @-Library) published in “non indexed” and “indexed journals” on worldwide scale according to the country of the author’s institutional affiliation

Figure 6. The absolute frequencies’ distribution of 2203 articles (filed in the repositories of the SoReCom “A.S. de Rosa” @-Library) published in “non indexed” and “indexed journals” by the continent Europe according to the country of the author’s institutional affiliation

Figure 7. The absolute frequencies' distribution of 587 articles (filed in the repositories of the SoReCom "A.S. de Rosa" @-Library) published in "non indexed" and "indexed journals" by the continent Latin America according to the country of the author's institutional affiliation

Figure 8. The absolute frequencies' distribution of 259 articles (filed in the repositories of the SoReCom "A.S. de Rosa" @-Library) published in "non indexed" and "indexed journals" by the continent North America according to the country of the author's institutional affiliation

Figure 9. The absolute frequencies’ distribution of 77 articles (filed in the repositories of the SoReCom “A.S. de Rosa” @-Library) published in “non indexed” and “indexed journals” by the continent Oceania according to the country of the author’s institutional affiliation

Figure 10. The absolute frequencies’ distribution of 89 articles (filed in the repositories of the SoReCom “A.S. de Rosa” @-Library) published in “non indexed” and “indexed journals” by the continent Asia according to the country of the author’s institutional affiliation

Figure 11. The absolute frequencies' distribution of 19 articles (filed in the repositories of the SoReCom "A.S. de Rosa" @-Library) published in "non indexed" and "indexed journals" by the continent Africa according to the country of the author's institutional affiliation

An even more impressive paradoxical effect emerges when the prominence of the three countries (United Kingdom, United States and Netherlands) in the distribution of 450 indexed journals including publications on social representations (Figure 4) by "country ranking" is compared with the geo-mapping of the entire scientific production (8348 items specifically related to social representations and communication, including also books, book chapters, conference presentations, web documents, manuscripts, university reports, master and PhD theses, etc.) filed in the SoReCom "A.S. de Rosa" @-library by continents and countries according to the affiliation countries of authors' institutions² (Figure 12).

A clear prominence of the European countries (especially France, UK, Italy, Spain and Switzerland) with 5488 publications, followed by the Latin American countries (especially Brazil, Argentina,

Mexico and Venezuela) with 2112 publications – among the list of 72 countries represented worldwide - emerges in the production-diffusion of the literature related to this scientific field.

Not only in terms of the prominence the geo-mapping of the literature produced by authors belonging to different Continents/Countries differ when comparing the restricted sources extracted by the 450 "indexed journals" with the entire production filed in the SoReCom "A.S. de Rosa's" @-library, but also in terms of the number of diversified countries and therefore of different geo-cultural contexts which contribute to the development of theory and research in the supra-disciplinary field of Social Representations and Communication. In fact the number of the worldwide countries represented in the entire corpus of 8348 items are 72 (among them 44 countries corresponding to author's publications

Figure 12. The worldwide % frequencies distribution of 8348 items specifically related to social representations and communication (including also books, book chapters, conference presentations, web documents, manuscripts, university reports, master and PhD theses, etc.) filed in the repositories of the SoReCom “A.S. de Rosa” @-Library by Continents according to the country of the author’s institutional affiliation

in journals indexed in both bibliometric data bases, 55 countries corresponding to author’s publications in not indexed journals), whilst the list of the “country ranking” included in at least one of the bibliometric databases is restricted to 29 (24 countries for articles indexed only in Isi-Web of Science for IF and 27 only in Scopus-Elsevier for SJR) (see Figure 4).

Issues, Controversies, Problems

It is evident from the statistical results visualized on the geo-maps that a serious epidemiological study on the diffusion of a scientific field cannot take into account partial sources of information (only articles and not also books; only articles in indexed journals and not the entire scientific production)³.

The analysis of the relevance of the scientific production also requires further refinement by cross-referencing many other interesting meta-data, like for example the inter-institutional collaboration “within” and “between” Continents and

Countries and even single Institution, paradigmatic approaches, preferred research designs and methodological options, thematic choices, etc.: by way of example, by analysing the significant link between the source of publication and the *thematic choice*, as evident on looking at the intersection between the top six “indexed” journals (selected by Impact Factor more than 10) and the topic chosen by the authors⁴, including multidisciplinary subjects (engineering or biochemistry, genetics and molecular biology, or agricultural and biological science, neuroscience, psychology) and just one alone in psychology, dealing with cross-cutting edge topics like biogenetics, nanotechnology, biotechnology (Figure 13).

This comment about the *relevance of the cross-cutting thematic choice, multidisciplinary domains and applied societal value of the topics* receives an external validation in the explanations provided by the authors of the 24 top cited papers – selected from an impressive initial search results including more than 13 million records (as of June 11, 2014) later refined, to include only

Figure 13. The top six indexed journals (selected by impact factor more than 10) including articles strictly related to social representations

full research articles while excluding reviews, editorials or book chapters - indexed in Scopus across various disciplines between 2001 and 2011 interviewed by Halevi and Moed (2014) “to seek their insight about why they think their papers are as highly cited as they are”. In fact one of the three observations advanced by them on the basis of the author’s comments is:

“The analysis of citing disciplines shows that research, regardless of its disciplinary origin, crosses subject-specific domains and has impact on a wide range of areas, some of which are quite surprising. It is plausible that the growing ability of researchers to be exposed to and read a wider range of literature encourages the transfer of knowledge from one discipline to another.”

The other two observations concern: a) the applied value for the knowledge development of the description of computer software and b) the inter-institutional and international collaboration among researchers interested on issues of global concern:

“It is noticeable that 4 out of the 10 articles featured here describe the development of computer software. The practice of citing computer software when used in a study is a part of this phenomenon. Regardless of the subject field, the

computational tools developed and written about are highly cited.

Out of the 10 selected articles, 6 are the result of a scientific collaboration between two or more researchers. Collaboration is seen across institutions and countries which could be a result of a common global concern to damaging phenomena related to the environment.” (Halevi & Moed, 2014)

Due to page limits it is impossible to include here the full list of the 450 “indexed” journals in which the 1492 (46% of our corpus) articles has been published and that we have categorised in different classes according to their ranking in the bibliometric databases Isi-Web of Science and Scopus-Elsevier and also of the list of 624 “not indexed” journals, in which the 1747 (54% of our corpus) articles have been published. These results deserve a specific publication, providing both a contribution to the systematic geo-mapping of the editorial channels for the dissemination of the social representation theory and research literature around the world, for illustrating the dynamic of knowledge in context produced according to the generational level of the scientists, their language and cultural constrains, the inter-institutional collaboration within and between countries and

continents etc. and at the same time a strategic tool for orienting the new generation of early stage researchers, faced by the bibliometric academic culture era for their career perspectives.

Solutions and Recommendations

The social representations of the new bibliometric culture (as an articulated set of opinions, beliefs, attitudes, values systems, social meanings, shared practices, etc.) should be set in relation not only with the authors' bibliometric profiles, but also with other variables that characterize the individual's scientific style and his/her options among academic practices such as:

1. Scientists' individual preferences to publish articles, book chapters or books, also taking into account the relation with their academic roles and generational levels;
2. Their preferred publishing strategies (as single authors, in teams of collaborating co-authors, etc.);
3. Preferred language in which to publish (national, English, other);
4. Internationalization of the scientists' careers (international collaboration, international project collaboration or leadership, study period abroad, etc.);
5. Their preferred approach: experimental/quantitative vs qualitative (and to what extent exclusively);
6. Several indicators of their scientific productivity and institutional recognition (research grants, awards, leadership roles, appointment to international committees, editorial responsibilities and so on).

FUTURE RESEARCH DIRECTIONS

In the near future we intend to extend this investigation in several directions, from the analysis of “The Impact of the Impact” based on textual literacy sources to the analysis of “the social rep-

resentations of the bibliometric culture” among the authors themselves, by using multiple survey methods of a projective and structured nature (free associations, interviews, focus groups, questionnaires, conversational data extracted from academic social networks). We plan to conduct the study on our worldwide academic community, the So.Re.Com. THEmatic NETwork (de Rosa, 2006), including its training structure (the European/International Joint Ph.D. in Social Representations and Communication: de Rosa, 2015b, 2016a), as a case-study in the social sciences.

This investigation will be further develop a multi-year research program led by de Rosa (2013a, 2013b, 2016b; de Rosa, Dryjanska, & Bocci, 2017) guided by the main goal of evaluating *the impact of the scientific production driven by the Social Representations theory in the social arena faced with social demand*. The aim of this project launched in 1994 is to take stock of the scientific field developed in more than 50 years by conducting an empirical meta-theoretical analysis of the literature on Social Representations, mapping the development of different paradigms, the related research methods, the thematic areas and their impact on the various applied fields within the multi-generational community of scientists and across different geo-cultural contexts.

CONCLUSION

Given the importance of the on-going controversial debate on academic quality evaluation systems based on bibliometrics (*see additional readings*) and knowledge production using big data, we are confident that this investigation will attract the interest of the scientists belonging to our scientific community and motivate them to collaborate.

Taking into account the debate which still animates and divides the community of scientists and institutional leaders, differently affecting not only their personal careers but also their intergroup relations, and their personal, social and scientific identities, according to the discipline, the genera-

tional level, and anchoring in different geo-cultural contexts, our study – supported by empirical data – may stimulate meta-reflexive discussion and exchanges of views among the members of our scientific community on the preferred publishing options and collaborative strategies in the current editorial and academic scenario.

It is out of the doubts, that also for the very well-reputed informetricians, that “more research is needed into communication, publication and citation and evaluation practices in Social Sciences and Humanities (a “science of SSH”)” (Moed, 2014). This is even truer in the era of the Science 2.0, characterised by the progressive computerisation of the research process, which is going to deeply modify the research practices (Nielsen, 2012).

Our scientific community will not be exempted from being affected by these fast modified research practices and the pioneer study presented in this chapter will need to be periodically updated to show a clear dynamic picture of the impact of the Social Representation literature over the world and across the disciplines.

KEY TERMS AND DEFINITIONS

Bibliometric Indexes: Indexes calculated on the basis of the number of citations and other factors, applied to scientific journals, and gradually also to other types of scientific production, such as conference abstracts and books. Among the main bibliometric indexes: Impact Factor (Isi-web of Science by Thomson and Reuters) and SJR (Scopus-Elsevier).

Big Data: According to some sources (Boyd & Crawford, 2012; Mayer-Schönberger & Cukier, 2013) data volumes in the range of petabytes and beyond, which exceed the capacity of most current online storage and processing systems; critical issues related to big data include their volume, velocity, variety, value and veracity. However according to Parks (2014: 255) data volume does not qualify in itself the “big data”, because the criteria should be relative to the “representativeness” of the specific field analysed.

Data Mining: Application of specific algorithms for extracting patterns from data; the term primarily used by statisticians, data analysts and the management information systems (MIS) communities who find useful patterns in data.

Geo-Cultural Context: Specific geo-location that takes into account the cultural characteristics of inhabitants, such as common language, history, customs or art; for example, insular, Mediterranean, North European, Latin American geo-cultural contexts.

Modelling Approach: A paradigmatic approach to social representations developed by de Rosa (2013a, 2013b) that integrates different methods and techniques based on multiple communicative channels (oral, textual, iconic, behavioral, etc.) coherently with the articulation of different theoretical constructs (like social representations, place-identity, social memory, attitudes, prior knowledge and channels of information, etc.) and dimensions (informational, evaluative, emotional, imaginal/experiential, etc.).

So.Re.Com. “A.S. de Rosa” @-Library: A multi-purpose web-platform for integrating

scientific documentation, networking and training in the field of Social Representations and Communication (So.Re.Com.) (de Rosa, 2014a).

Social Representations: A theory developed by Serge Moscovici (1961/1976), which – according to de Rosa (1994) can be operationalized on three different levels: a) social representations as *phenomenon* – “ways of knowing” characteristic of social reality that emerge in daily life during interpersonal communication and are directed toward comprehension and control of the physical-social environment; b) *theory* of social representations – the collection of conceptual definitions, methodological operations and formulation of constructs that have social representations as their object; c) *meta-theory* of social representations – the collection of critical comments, ripostes and comparisons with other theoretical models which emerges from the critical debate on the theory of social representations. For a stock of the wide scientific field developed in more than 50 years since 1961 see de Rosa (2011, 2013a), de Rosa & d’Ambrosio (2008).

ENDNOTES

¹ The source of data presented in this section is equal to 3234 rather than 3239 articles, because it was impossible to identify the institutional affiliation for 5 authors and therefore to include them in the geo-mapping.

² At the time of writing this article (March 2016) it has been possible to identify the country of the author’s Institution affiliation for 8348 items of the 8740 references specifically related to social representations and communication (including also books, book chapters, conference presentations, web documents, manuscripts, university reports, Master and PhD theses, etc.) filed in the repositories of the *SoReCom “A.S. de Rosa” @-Library* and therefore to proceed with statistical analysis the ranking by

continents and countries in the production/ dissemination of the literature.

- ³ It should be noted that currently Scopus-Elsevier and WoS start to cover - at different extent - also books and book chapters upon review of quality standard of publishing houses, but - despite the big investment es-

pecially by Scopus in the field of humanities and social sciences – the sources are still limited.

Information and Its Conceptual Perspectives

José Poças Rascão

Institute Polytechnic of Setúbal, Portugal

INTRODUCTION

Information has attributes/positivist concepts that some authors use to better understand it. Others are critical about information subjectivism. This chapter discusses conceptual perspectives of information. The aim is to study the concepts of information from some areas of knowledge of the social sciences, cognitive and business looking to propose a concept of information in the field of information science. The methodology of the study is formed by bibliographical research. It is concluded that the concept of information is still in full development.

The concept of information depends on the perception of information (Kirk, 1999). Although this is not something that shocks, raises some interesting questions and research opportunities. For example, as we get the information? What are the claims, limits and consequences of these perceptions? Can these perceptions be described and why?

Fundamental Concepts

The perception of information¹ not only influences our view of information, but also our perception of information system (Klein & Hirschleim, 1987), our perception of communication (Mokros, 1993, Schement, 1993) and the conduct of research (Newman, 2001, Schement 1993). This means that the perception of information, which we prefer to call information concepts, have a profound influence in the field of information science.

The information concept fascinates many scientists from different fields such as biology,

psychology, computer science, sociology, economics, management, political science, statistics, philosophy, communication and information studies (Mokros, 1993, Newman, 2001, Ruben 1993, Schement, 1993). In all these fields the information is an important concept, but at the same time none of them can claim the information as being relevant only for them.

The information should be viewed as an interdisciplinary concept. This means that the concepts of information must be studied in different disciplines. It also means that the concepts of information are not only relevant in the field of information science.

On the concept of inter-disciplinarity of information no deal has emerged and no unifying theory is presented as imminent (Schement, 1993). When information is defined “the abundance and diversity confuse us” (Braman, 1989, p. 233). A tempting conclusion that we reached is that the meaning of information depends on the context. While many argue that we need a theoretical perspective of information (Devlin, 1999, Aefiner, 1999, Newman, 2001). We do not intend to define a theoretical perspective, but only present the different concepts in different disciplines, as well as a critical analysis of the different concepts.

Newman (2001) describes a variety of concepts in different sciences that can be grouped as follows:

- Probabilistic concept;
- Concept of information processing;
- Ecological concept of info;
- Social and organizational concept of information.

The probabilistic concept of information is that low-probability events represent high information content. An important application of this concept is the information theory Shannon and Weaver (1949, in: Newman, 2001). In this theory the mathematical representation of the transmission of a message is presented as if the information was a measure of predictability.

Logic, cybernetics and philosophy also correlate the information with the probability (Fisher, 1934, Carnap & Bar-Hillel, 1952, Popper, 1965, Mackay, 1969 in: Newman, 2001). But these concepts differ in important ways, as for example, in the interpretation of probability and on the semantics of the information. With respect to the semantics of the information, many concepts see the information as reduction of uncertainty.

The concept of information processing (or cognitive concept) focuses on the thought of cognitive psychology. However this concept, thinking and information processing are seen as analogous. It is clear that the information is the product of thought and that increases knowledge about anything. The model of the cognitive process and the internal representation are the first concern of this approach.

The concept of ecological information is not created, but is present in the world, from the environment, in a given situation. Organizations collect this information actively from the outside world. An important extension of the ecological approach is the situation theory. This reconstructs itself in a mathematical basis, and makes a clear distinction between information (content or information) and its representation.

The social and organizational concept of information falls within the sphere of labour: work associated with the concept of information economy. In this category, the information relates to the processing of the same and the information pyramid model is often used. In this model a data must be processed to produce information and the information should be processed to produce knowledge.

An important ingredient of the information economy is the quantification of “work information” and “information product”, used among other things to show the importance of knowledge in the modern economies (Wallerstein 2000, Murteira, 2001, Brandt, 1995, Nicholas, 2000, Handy, 1990, Hauknes, 1999). In the well-known effort of Porat (1997, in: Newman, 2001) it is clear that the information is associated with the reduction of uncertainty.

The research of information science focuses on the process of information in the Organization and the need for information of managers in support of decision-making. The satisfaction of this requirement can result in a reduction of uncertainty, which contributes to a better decision-making (Schement, 1993).

Philosophical Concept of Information

Belkin (1978) contributed with many studies for an important problem of information science: the question of the definition of an appropriate concept of information for information science. Although Belkin discusses the concepts of information used only in information science, many of these concepts were originated from other fields and/or are used in a wide variety of these (Belkin, 1978, p. 82):

- **Information as Fundamental Category:** The information is seen as something that is essential to the existence of the universe, as the base, but a different category of matter;
- **Information as Property of Matter and Consciousness:** The information is not regarded as a special category, but as property of matter (i.e., objective information) and or property of conscience or reflection of an individual (that is, subjective information);
- The information as a social-scientific information is based on the classification

of Mikhailov, Chernyi and Giliarevskii (1975, in: Belkin, 1978). This classification divides the intuitive idea of social and non-social information, semantics social information and not semantic and scientific and unscientific semantic information. According to Mikhailov, Chernyi and Giliarevskii, the information is limited by the social science;

- **Information as Event:** Information is seen as the expression of the mental image that occurs when we receive a message;
- **The Information Framework:** The information is seen not as an event, but as the resulting structure for this event. Example, information is the resulting structure in the mind of a sensory data or some experience;
- The information as a probability of occurrence of an event comes from Information theory of Shannon and Weaver (1949);
- **Information as Message:** Vague concept in which the information is confused with the content of a communication.

Concept of Information in the Context of Decision-Making

Braman (1989) suggests a hierarchy of information definitions that are used in the context of decision-making. The hierarchy is based on three dimensions: the level of opportunity, the level of complexity and associated with the power (which is guaranteed for the info, streams and use). These dimensions group the definitions of information into four groups:

- Information as a resource;
- Information as something useful;
- The information as a standard perception;
- The information as an essential feature of society.

Information as a resource is associated with the lowest level of opportunity, complexity and power, while the information as essential feature

of society is associated with the highest level in these three dimensions.

- Information as a resource treats the information as an isolated and distinct entity without power in itself. The information is divided into the parts that make up the body of knowledge or information flows in which can be organized (Braman, 1989, p. 236).
- The information as useful thing focuses on the process of exchange of information between people. This concept requires the chain production, through which the information gains economic value (Porter, 1980). The chain includes steps such as the creation, processing, and distribution. This implies a greater complexity of social structure “including suppliers, customers and the Organization in order to keep the market” (Braman, 1989, p. 238).
- Information as a standard perception requires the information and the context. The information “has a past and a future, is affected by the stimulus of casual factors and the environment” (Braman, 1989, p. 238). Compared to information as useful thing, the scope of the phenomenon covered by this concept is extended. The information can be used to articulate social structures. This definition sees the information as an element of reducing uncertainty.
- Information as essential feature of information-oriented society as “an active function built in context” (Braman, 1989, p. 239). The information becomes an actress who affects the environment and creates a social structure.

This definition treats the information as an essential feature of society. Is applied to all phenomena and processes in which information is involved and can be applied to social structure with some degree of articulation and complexity (Braman, 1989, p. 241).

Concept of Information Process, as Knowledge and as Thing

Buckland (1991) identifies three “primary uses” of the term information:

- The information as a process;
- Information as knowledge;
- Information as thing.

The information process refers to the act of informing/be informed. When someone is reported, what he/she knows is changing. The “information as knowledge” refers to what is perceived as process information. Is the knowledge that is communicated. Buckland (1991) see information as reduction of uncertainty, as a special case of “information as knowledge”.

Some information increases the uncertainty. Information as thing refers to things that are looked at as being informative, things become informed. Buckland also examines different things (data, text, subject material, events) and concludes that the whole thing is or should be informative. Argues that the virtue of being the information as thing is situational and depends on subjective judgments.

Buckland (1991) summarizes the main tree concepts of information, in terms of two distinctions:

- Between entities and processes;
- Between intangible and tangible assts.

Buckland (1991) distinguishes four aspects of information, but only three regarding the use of information. The fourth aspect of information is information processing. This refers to the execution, manipulation and deduction of new forms or versions of information, as a thing.

Concept of Inter-Disciplinarily of Information

Ruben (1992, 1993) has different propositions to “provide an inter-disciplinarity in the relationship information-communication” (Ruben, 1992, p.

22). Ruben does not justify this classification and does not refer any example of these concepts in the literature.

However sees the information as an inter-disciplinary concept focused on the relationship between information and communication. Here explicitly outlines a wide variety of fields, such as biology, economics, and Cybernetics, mathematics, sociology and communication studies:

- The information has potential significance for a living system, but this potential is not yet updated;
- The information is that which has been transformed and configured for use by an individual;
- The information includes the sharing of information/knowledge base of society and other social systems.

Concept of Information in Communication

Schement (1993) reviews 22 definitions of information from different fields, such as economic, physical, information and communication and information science. Although his focus is the study of information and communication, he parses their inter-disciplinarity, because the definitions of the different fields are compared. On the basis of these definitions distinguishes “fundamental terms whose sketch of current of thought is the nature of the information” (Schement, 1993, p. 7).

Information as thing treats the information as a thought, being a thing (non-material). According to Schement this concept is the most widely used of the three concepts. Two examples of this concept are:

- “information is an entity; but a thing which has no mass or energy” (Diener, 1989 in: Schement, 1993);
- The information is a consistent collection of data or messages organized that have meaning or may be used by the human system (Ruben, 1988 in: Schement, 1993).

The information can also be a process. This concept of information process sees the information as the phenomenon to inform or to change a given situation. An important sub-theme of this concept is the vision of the information as the reduction of uncertainty, a common view among economists, managers and computer scientists.

The last concept, the information as the product of manipulation is seen as thought is something that must be manipulated to exist. Example:

Information is produced, as a result of a process on the data. (Hayes, 1969, in: Schement, 1993)

According to Schement these perceptions of information are related to different perceptions of communication. He argues that these two concepts are inextricably bound by each other.

Information Concept in the Real World

According to Gelepithis (1999) information is the central concept for the community of information sciences. A considerable number of disciplines related to information has been engaged in the development of other closed concepts, related to information (ex: sign, symbol and meaning (Shannon and Weaver, 1949, in: Newman, 2001).

Gelepithis (1999) is concerned with the clarification of these concepts and their consequences in the fields of information science. However its proposal is not present in the table of contents of the various concepts of information in different disciplines. Gelepithis (1999) presents seven concepts of information:

- The information in terms of the probability of a signal;
- The information as a state;
- The information in terms of knowledge and meaning the mental level and as a mental entity and not material;
- The information in terms of concept of the sign as a primitive;
- The information conceived in terms of the world tree;
- The information in terms of true condition;
- The information as a basic property of the universe.

The problem with these concepts is that they are very brief. The information in terms of sign as a primitive is referred to by Stamper (1985) in that he proposes the semiotics (sign theory), as an appropriation of the information theory (Shannon and Weaver, 1949). He argues that the idea of a sign is “the very primitive in which is based the information science” (Gelepithis, 1999, p. 195).

The signals can be described as physical things-objects, events, or properties of objects and events — and are available to represent a function in human behaviour. The information is in fact a measure of some property of a signal. The measures differ from each other (e.g. entropy measure and subjective measure) and in addition information has different meanings.

The information conceived in terms of Popperian world tree design is the basis of Popper & Eccles (1977) they argue that we just accept things as real if they can interact with material things. He distinguishes three realities or three worlds:

- 1 World:** The world of physical objects and states;
- 2 World:** The world of states of consciousness (e.g., subjective knowledge, experience of creative imagination);
- 3 World:** The world of knowledge towards objective (e.g. products of the human mind, theoretical systems, scientific problems).

According to Popper these worlds interact with each other. However still unclear what Gelepithis (1999) is mean by information conceived in terms of these three worlds.

CRITICAL ANALYSIS OF THE CONCEPTS OF INFORMATION

Philosophical Questions

It is important to make the distinction between information and its representation, being one of the most common misconceptions confuses information with its representation (Devlin 1999, p. 27). Buckland (1991) states that the representation is often seen as information and Ruben (1993) stresses that seeing the representation as information is “appropriate and useful for some purposes.” So the information as something material (representation) can be seen as an important concept.

Atmanspacher (1999) and Fuchs-Kittowski (1999) describe the information as something material or not, and the philosophical question is related to the distinction between material and non-material². Information as material thing is related to the human mind and is seen for example by:

- Buckland (1991) – Information as thing;
- Ruben (1993) – Information about the surrounding environment;
- Belkin (1978) – Information as property of matter.

The concept of information as useful and as a resource is basically variations of information as something material. According to Haefner (1999) information has a material level, but in reality does not exist, though Buckland (1991) claims that we often use the word information as if it were something material.

The concept of information as mental thing is often equalled to knowledge, (Buckland, 1991, Ruben, 1993, 1978, Belkin Gelepithis, 1999, Anderson, 1980, in: Newman 2001). According to Miller (2002) this is also a habit in the literature of knowledge management. He alerts us to a vision because the information itself has no intrinsic meaning. Information can provoke or evoke the thoughts of others³.

There are also some researchers who relate explicitly to information as something different besides of matter and mind. For example for Devlin (1999) “information is not physics nor is in the mind of the other: our thoughts are located inside of our heads, but the information is out of it.

The information exists somewhere between the physical and the mental world. It is reasonable and wonderful to see the information as something that exists in the public domain. Gelepithis (1999) and Belkin (1978) also refer to something other than matter and mind.

Gelepithis (1999) presents a concept in which the information is a basic property of the universe and Belkin (1978) introduces the concept in that the information is a key resource, such as the base. Another example is Fuchs-Kittowski (1999) and Zikmund (2000) who argue that the information is neither in the article nor in the mind, but makes the connection between the physical environment and the ideal.

One can criticize or comment these visions, but we just summarize the possible views as regards to the position of the information found in the literature:

- Information as subject material;
- The subject of mental information;
- Information as an abstract entity (not material or mental)

We hold these positions as information changes as thing; the information is treated as an object, an entity, a thing. The three variations can be found in the literature: the Based on the similar description between information concepts groups we concluded that the information as thing information and as process are the basic concepts of information, is informational, a mental object and an abstract entity referred to the context.

The Information vis-a-vis Social

The constructed nature of information is also present on the concepts of Braman (1989) “perception

of a pattern” and “constitutive element of society”. Also the concept of Ruben (1992) refers to the social nature of the information. The information includes the sharing of information/knowledge, bases of society and other social systems. Belkin (1978) refers to “relational system of scientific facts, theories, hypotheses, and laws, publications that are the result of human observation, of nature and of itself”.

When we removed the restriction to scientific information we obtain greater resemblance to the concept of Ruben. Also the world of Popper 3 (1977) refers to this concept of information (Tully 1985). On the basis of this research we suggest the third basic concept of information, information as social construction. This concept refers to the sharing and building the information base of the social system.

Information as Probability

Belkin (1978) and Gelepithis (1999) distinguish the concept of information related to the likelihood and both refer to Shannon (1949). In the formulation of Shannon information as feature selects the desired message out of possible messages. The amount of information associated with the selected message is related to the probability of this message be sent. The expected message does not result in information⁴.

The concept of Shannon (1949) has been used by many other fields, more than was originally proposed: telecommunications. At the same time the use of the concept of information of Shannon’s is much criticized (Belkin, 1978, Borgman, 1999, Bryant, 2001, Callaos, Callaos, B., (2002) because it has a very limited vision of the concept of information⁵.

Sveiby (1998) points out that Shannon was unhappy with the word information on his theory and he was advised to use the word “entropy” rather than information. To Shannon information equals “entropy”, i.e. chaos/confusion. This contradiction with Wiener (1948, in: Sveiby, 1998) takes into account that the information is the same as

the structure (“negative entropy”)⁶, that is, “to play the world’s structured” (Sveiby, 1998, p. 4).

Although the concept of Shannon information is criticized has also been used by some researchers as a point of departure. However we consider the concept of Shannon information, as an information base concept. The concept of information as structure, which seems to contradict the concept of Shannon, has been found in Belkin (1978) and Gelepithis (1999).

Concepts of Information Related to Information as Thing

We argue that the concepts presented earlier might be related with the information like this: the information as the product of manipulation (Schement, 1993)), the information as a resource, the information as convenience (Braman, 1989), the information as data and the information as message herself (Belkin, 1978).

Information as the Product of Manipulation

We see the concept of Schement information (1993), as the product of manipulation, as an example of how information thing. Remember the description of this concept: “one thing that should be handled with the purpose to exist”. With this thing a process can be associated; in this case a process of manipulation.

Information as a Resource and as a Convenience

Form the description of Braman (1989) it can be concluded that the information as a resource and as a convenience can be seen as an example of information as thing (Lauer 2001, p. 43). Outlines the information as a resource, as an entity, as a commodity and as a resource with economic power⁷.

According to Braman (1989) the focus of the attention of the information as a convenience is the process of changing the information. In other

words, when we see information as something we can still focus on the procedural aspects associated with this thing.

The Message Itself

Belkin (1978) proposes the concept of information as “the message itself”. This concept is not described clearly, but seems to refer to “message content”. In terms of basic concepts this means the information as no material thing (e.g., mental object or abstract).

Data, Information, and Knowledge

Although the concepts of data and information with interchangeable frequencies are used, these are not the same thing. Information is not the same thing as data, although the two concepts are often confused by the subtle distinction between the two concepts is essential.

The data does not carry any sense or meaning of the facts, images or sounds, since they lack relational elements essential to the establishment of a complete meaning, requiring a relational structure internal to a cognitive purpose. The data become information when its creator joins them meaning (Davenport and Prusak, 1998).

Data are partial representations of facts, images or sounds, have no meaning by themselves, since they do not lead to the understanding of the facts or situations and converted into information, when introduced into an information structure (global) acquired (Steven Alter, 1992, Davenport and Prusak, 1998, Keith Devlin, 1999).

The concept of information as is commonly seen in the field of scientific research. In this vision of the information as given with meaning attributed (Checkland and Howell, 1998, p. 95) or simply: $\text{information} = \text{data} + \text{meaning}$ ^{8,9} (Devlin, 1999, p. 33).

While it seems logical to think that this meaning is given by humans, Checkland and Howell (1998) point out that some information in the scientific

field definitions assume that the machine assigns meaning. This suggests that there is only a single meaning related to the information.

The concept of information can be understood under very different perspectives. The information is an object created by man, having the purpose to represent an identifiable event for him in the real world, integrating and relating a set of records or data, (Le Moigne, 1979, Steven Alter, 1992). Is the difference that makes the difference (Bateson, 1972).

In terms of equation:

$\text{Information} = \text{data} + \text{meaning}$

When a person internalizes the information to the point that one can use, we call it *knowledge* (Zikmund, 2000). This is a fluid mixture of experience, values, contextual information and expert insight, structured to provide a framework for evaluating and incorporating new experiences and information.

Knowledge is information as valid and accepted, integrating data, actions, information and sometimes hypotheses. The knowledge needs someone triages combine and interpret the information. The information can be considered as a “*substance*” which can be acquired, stored and possessed by a person or group and transmitted from person to person or from group to group.

$\text{Knowledge} = \text{Information internalized} + \text{ability to use}$

Knowledge is thus a mixture of information, experience and understanding which provide a structure that can be applied in the evaluation of new information or new situations (William Zikmund, 2000).

The knowledge is fundamentally and inherently inside people. These are much more complex and unpredictable individual level than an entire society, so it is not surprising that knowledge work much harder to get that information. The

knowledge exists primarily within the people, is an integral part of the human unpredictability and complexity (Davenport and Prusak, 1998).

Reduction of Uncertainty

The reduction of uncertainty is often related to the concept of probability. The probabilistic approach more the vision of reducing uncertainty with the function semantics; the effect of information is the reduction of uncertainty. This reduction depends on the likelihood of the message being sent.

The concept of uncertainty reduction of Belkin (1978) sees the reduction of uncertainty as a particular effect; It changes the State of knowledge. Braman (1989), Buckland (1991) and Schement (1993) see the reduction of uncertainty as an instant or an example of the concepts proposed by them.

All these aspects seem to be necessarily related with the sense of uncertainty. Only based on linguistic Association we see the reduction of uncertainty as a mental process and so the concept of information as uncertainty reduction as a special case of case information as a process.

Information as Structure

Belkin (1978) distinguishes information as structure and Gelepithis (1993) distinguishes information as requested. Gelepithis does not make the distinction of this concept, is unclear about what is this concept. It seems to us that order and structure refer to the same thing.

Belkin (1978) refers to an effect of information, that is, the change in structure. This change in structure can occur in multiple “systems” (Belkin, 1978, p. 79), for example (or structured container image). In the case of the structure of the mind, this concept refers to something mental; the mental thing or the mental process. In the description of Belkin (1978) remains unclear what he meant with the structure of other “systems”.

It is important to note that this concept has no relationship with the Wiener (1948), the information structure (Belkin, 1978, p. 79), which

describes the information as “a structured part of the world”. This description of Wiener (1948) seems to see the information as a thong. Sveiby (1998) points-in the aftermath of the concept of Wiener, which is often suggested by “adding value” or selection, interpretation and information update, the highest of the information (e.g. knowledge) that can be retrieved¹⁰.

True Condition

Gelepithis (1999) proposes the concept of “information in terms of real condition”. It is not clear what he means by this. Other researchers do not describe this concept, by which we consider not to be very important and is not a basic concept.

Signal as Primitive

It explain briefly what the meaning of signal as primitive is and its relationship to information. Information has different meanings, depending on the area of semiotics. On the basis of Stamper (1985) is the description of these meanings. We argue that the information as probability is an important empirical concept. The information as given (which relate to the information like thing) is an important concept for the syntax.

For the semantics we suggest the information as mental process that is pragmatic and even information as social construction is an important concept. So the concept of information as a sign of a primitive is not in fact a simple concept; It is a basic principle of semiotics and organization work of various ideas with regard to information.

Popper

Gelepithis (1999) also proposes the concept of “information conceived in terms of design Properian of the three words”. Previously we explain briefly these three words and we would like to remind you that it is not clear what Gelepithis (1999) mean by this concept. Although this is true, it is appropriate to recall that the basic concept of the

three trees can be related to these three words of Popper (World 1, World 2, world 3).

Information as something becomes a material variation of the world 1, information as something becomes a variation of information process for the world 2 and information how thing is an abstract variation of information as social construction into the world 3. Information only as probability we do not know where to place it.

Some concepts are used in various areas (e.g. the reduction of uncertainty) and may be related to more than one basic concept. Because most concepts are related to the basic concepts and therefore argue that these fundamentals reflect (or feature or summarize) previously concepts of information.

We argue that the basic concepts reflect the most important uses of information in the literature. The main argument is that the concepts presented in previously (in which the basic concepts are based) are in our opinion a pure reflection and understanding of the areas in which the information is perceived in the literature.

FUTURE RESEARCH DIRECTIONS

The discussion presented aimed to propose the understanding of the concept of information, in the context of information science under the systemic perspective, whereas epistemological, scientific and practical.

Although you can delimit the relevant study and distinguishable object, the information, to the information science is essential to establish an epistemological justification of the concept of information, as a basis for the understanding of this object, in all areas of knowledge.

The feature of information is its inter-disciplinarity character, typical of areas of expertise that arise in the context of Post modernity. Therefore, just as in information science, methods, models and theories in the area are derived from other areas of knowledge.

The discussions raised on the concept of information are of the utmost importance to the information science and society. Who knows, therefore, that the work does not end here. This is only their embryonic stage.

FINAL CONSIDERATIONS

The concept of information has been consolidated as a positivist paradigm in information science with the incorporation of theories, concepts and methods of various areas of expertise and manifests itself in various subareas that comprise the information science.

The paradigm shares with positivism all its features, as well as its limitations, being the principal the inability to capture what the method can not handle to grasp: the subjective information, with various interpretations and inserted into the historical-cultural experience.

Several studies show the complexity of the phenomenon-information-to theories proposing to study it, including information science, on the one hand, and its binding to the humanities and social sciences, on the other. The positivist nature studies reaffirm the concept of information in objectivist perspective, without consideration the subject and the socio-cultural contexts, which takes the information as given and not as a construction.

KEY TERMS AND DEFINITIONS

Data: The data does not carry any sense or meaning of the facts, images or sounds, since they lack relational elements essential to the establishment of a complete meaning, requiring a relational structure internal to a cognitive purpose.

Information: The information as “data with value for decision making”. The description of this concept refers to the effect that information, such as reduction of uncertainty, we consider, as an example of how to process information.

Knowledge: The information can be considered as a “substance” which can be acquired, stored and possessed by a person or group and transmitted from person to person or from group to group. The information has certain stability and perhaps is better faced as existing at the society level.

Objective Information and Subjective Information: To distinguish two main concepts of information: objective information and subjective information. In its systemic concept, the information will be considered: subjective information quadruple objective information, and both processes that relate.

Profitability of Information: “Information is a complex concept, ubiquitous since the emergence of life and inherent in any evolutionary process and thus served and continues to serve as a framework for reflection so much in biology, physics, psychology, in management, in Linguistics, as in many other branches of science”.

ENDNOTES

- ¹ The distinction between definition and perception, is that the definition is what characterizes the defined phenomenon, whereas the perception (concept) is the process of looking at the phenomenon. Accepting the idea of perception becomes easy to look into the usefulness of perception with more reason than the universally true definition (Belkin, 1978, p. 58).
- ² Descartes is known for his clear separation between mind (not material) and body (material). This is sometimes called the Cartesian form.
- ³ Sveiby (1998) points out that many scientists in experimental psychology and the science of information see information as meaning herself, information has a meaning independent of the user.
- ⁴ In general terms may mean that information is just information is something new. Another step is to say that the information should make a difference. “information is the difference that makes a difference” (Bateson in: Bausch and in 2000: Sveiby 1998).
- ⁵ Shannon wasn’t very interested with the meaning and the semantic aspects of communication. He should focus on the problem of engineering (see e.g. Sveiby 1998).

- ⁶ According to Bryant (2001) this contradiction disappears once resulted in the focus of Shannon (along with Weaver), in the performance potential of technology by passing the signal and Wiener focused him on human participation.
- ⁷ Treat information as a resource or convenience has given rise to many discussions in the economic literature (Babe, 1994, Belkin, 1978, p. 64/5, Braman, 1989 p. 238).
- ⁸ I've always been curious that a unit (Physics) of the two operands is always a formula.
- ⁹ In this view the information has an intrinsic meaning.
- ¹⁰ The relationship between knowledge and information is a question debated in the literature, especially in the literature of knowledge management (AlHawamdeh 2002, Wilson 2002). One problem is that different perceptions of knowledge exist.

Open Data Repositories in Knowledge Society

INTRODUCTION

“Open means anyone can freely access, use, modify, and share for any purpose subject, at most, to requirements that preserve provenance and openness. (Open Definition, 2015).” Open data is data that can be freely used, re-used and redistributed by anyone - subject only, at most, to the requirement to attribute and share alike (Open Data Handbook, n.d). The term “Open Data” thus refers to data and information beyond just governmental institutions and includes those from other relevant stakeholder groups such as business/industry, citizens, Non Profit Organizations (NPOs) and Non Government Organizations (NGOs), science or education including the World Bank, the United Nations, The Guardian and the Open Knowledge Foundation (Bauer & Kaltenbock, 2012). Open data is regarded as an essential component of modern day research as it facilitates carrying advance research activities in different subject domains at much broader levels. Open Data is an important resource for supporting decision making activities in Government agencies; research Institutions, Higher Educational Institutions etc. The research activities as well as policy making decisions are highly benefited by the availability of open data. Many countries have come forward to embrace the concept of Openness especially facilitating Open access to government data as such data is deemed to be public data by law. The open data

facilitates transparency and democratic control, participation, self-empowerment, improved or new products and services, innovation, improved efficiency and effectiveness of government services, impact measurement of policies, new knowledge from combined data sources and patterns in large data volumes. Open data as such is of much economic importance and is being reused world over in different setups. It improves government efficiency in addressing different issues concerning common people. It is paving ways for modern social fabrication and adding economic values to the existing data sets for efficient utilization resulting in new knowledge creation and more specializations. There should be no restrictions to its reuse like legal, financial or technological etc (Open Data Handbook, n.d).

The key requirements for Open Data include free availability of data and access and also format for redistribution and reuse of that data (SPARC, 2013). Good open data can be linked to so that it can be easily shared and talked about; is available in a standard, structured format, so that it can be easily processed; has guaranteed availability and consistency over time, so that others can rely on it; is traceable, through any processing, right back to where it originates, so others can work out whether to trust it (Open Data Institute, 2015). Harnad (2005) discusses that open access has two complementary routes: the gold road and the green road. Publishing in open-access journals

is the golden road. It calls on publishers to adopt open access policies whereas green road calls on researchers to self-archive their works in institutional repositories and publishes it on the author's institutional Web site. The more data is made openly available in a useful manner, the greater the level of transparency and reproducibility and hence the more efficient the scientific process becomes, to the benefit of society. This viewpoint is becoming mainstream among many funders, publishers, scientists, and other stakeholders in research (Molloy, 2011).

Heery and Anderson (2005) define digital repositories as digital collections in which the content is deposited and organized in a database, either by the content creator or some other means. Such a repository is based on an architecture that manages content as well as metadata and offers a minimum set of basic services while the purpose of a digital repository is to store and manage learning objects (McGreal, 2007). These repositories provide services to faculty, researchers, and administrators who want to collect research, historic, and creative materials (Drake, 2004). One characteristic common to all open repositories is the fact that they have been created by using software packages with open source licensing and developed by working groups linked to the open archives initiative community. This is based on the implementation of a shared protocol: Open Archives Initiative-Protocol for Metadata Harvesting (OAI-PMH). The essential feature of OAI-PMH is that it provides great ease of implementation because components of the OAI model basically involve a metadata harvester, a search and retrieval interface and a shared repository made up of a collection of individual repositories. These are combined with a set of requests and responses made through the hypertext transfer protocol (Bravo & Diez, 2007).

Data Repository is a logical partitioning of data where multiple databases which apply to specific applications or sets of applications reside (Online Learning, 2014). It is a somewhat general term used to refer to a physical or logical destination

or place designated for data storage for multiple databases, records or files. The term data repository can be used as either a local location that is directly accessible to the user without having to travel across a network or for a network location (Research Data Alliance, 2014). Generally, a data repository serves as the centerpiece of an open data effort. It serves as a central location to find data, a venue for standardizing practices, and a showpiece of the use of that data. Some repository software allows syndication, permitting other organizations to automatically incorporate their own data (How to Open Data, 2015). Open data repository as such is the warehouse of open data, where data warehouse refers to central repository for all or significant parts of the data collected. It includes data that can be freely used, reused and redistributed by anyone (National Informatics Centre, 2013).

Open data repositories as such provide ample opportunities for the scientific communities not only to showcase their research but making their research assets visible and distinct at global level. These repositories thus incorporate much richer features including:

Web Syndication

Web syndication refers to the creation of web feeds available from a particular website in order to provide people with update of recently added content. The two main formats of web syndication include RSS and Atom. This technology is incorporated in open data repositories to make their users updated by retrieving latest information from sites of interest and informing them about the changes in the content.

Support for Varied Data Types

These repositories also have been maintained to host different types of Open Data sets with the help of different software technologies. These include images, graphs, audio-visual data, network-based data, etc. These types of data have been used by

repositories to make their content more authentic, meaningful, attractive and easy to understand to increase the use of resources in these repositories.

Persistent Identifiers

Persistent identifier is an identifier which provides an appropriate representation of the resource and can be updated when resource change location so that resource will be available for longer period of time. Open data repositories make use of different persistent identifier systems like Digital Object Identifier (DOI), Uniform Resource Name (URN), Persistent Uniform Resource Locator (PURL), hdl, etc to make their available data persistent, globally accessible and citable over longer period of time and across platforms.

OAI-PMH Complaint

The Open Archives Initiative Protocol for Metadata Harvesting (OAI-PMH) provides an application-independent interoperability framework based on metadata harvesting. OAI-PMH complaint has great ease in implementation and flexibility to adapt to any context to provide information about any sort of resource, whether physical or digital (Bravo & Diez, 2007). OAI-PMH compliance enhances the visibility of the repositories and hence increases its usage that encourages use of it by these repositories.

BACKGROUND

The development of open data repositories started with the open access movement which took concrete shape and was described in declarations, the Budapest open access initiative, 2001 and The Bethesda statement on open access publishing, 2003 (Suber, 2003). Berlin Declaration 2003 brought together international experts with the aim of developing a new web-based research environment using the Open Access Paradigm as a mechanism for having scientific knowledge

and cultural heritage accessible worldwide (Max Planck Society, 2015). The exchange of scientific information is vital for the establishment of open access archives, which can prove as a faster, cheaper, and simpler route to reach the ultimate goal of universal open access in the future (Kirsop, Chan & Arunachalam, 2007). Trencheva and Todorova (2014) in their study on Open access to scientific information concluded that Librarians and information professionals are called to help their users to take advantage of the extraordinary potential of OA and participate in the creation of repositories and to encourage publication in the available repositories of scientific content. All these factors lead to development of open repositories as worthy information channels for scholarly communication. Many studies focused on open institutional repositories (Chang, 2003; Yeates, 2003) revealed that institutional repositories provide a way to display the research development of an institution through orderly collection, organization, preservation and providing access to its research output.

Repositories can be further categorized into Disciplinary and Institutional Repositories. A disciplinary repository is subject-oriented, without organizational or geographic limit. These types of repositories collect and provide access to the literature and scholarly outputs for a single discipline or a set of related disciplines. These repositories accumulate their data through authors' self-uploading of articles. Disciplinary repositories like PubMed or arXiv use standard set of content types and dissemination mechanisms and have few interaction tools (Adamick & Zellen, 2010). These aim to provide a rapid and convenient way for scientists to exchange their research results with colleagues (Luce, 2001).

On the other hand Johnson (2002) defines Institutional repositories as digital archives of the intellectual products created by the faculty, researchers, and students of an institution and accessible to end users both within and outside the institution. Lynch (2003) states that "An institutional repository is the collective intellectual

output of an institution recorded in a form that can be preserved and exploited. It collects, manages, disseminates and preserves scholarly works created in a digital form by faculty and students in universities and colleges. It can offer a set of services including digital content, submission, organization, access, distribution and preservation". Crow (2002) states that their content may comprise of preprints and other works-in-progress, peer-reviewed articles, monographs, data sets and other ancillary research material, conference papers, electronic theses and dissertations, and gray literature. Institutional repositories provide a centralized framework in which faculty members, researchers, scholars, and others can build their digital collections. These repositories provide digital collections with an infrastructure and stability that can sustain changes (Gibbons, 2004).

Trends in Open Data Management and Availability

Open public data are not only considered as an economic asset that can contribute to new products, services and efficiency gains, they are also seen as a key driver in the promotion of transparency (European Commission, 2011 as cited in Hellberg and Hedstrom (2015)). There are many versions of "open data" such as open data, open government data, linked open data and public sector information. "Government data" is explained as "any data and information produced or commissioned by public bodies". "Open Government Data" is government data that is openly available. It has been defined by eight principles, which outline that to be assessed as open; the data should be complete, primary, timely, accessible, machine-processable, non-discriminatory, non-proprietary and license-free (Ubaldi, 2013). According to Lluís, (2014) Open Data projects could reinforce the strategies of records preservation in databases and could mean an opportunity for historical archives if they take charge of the maintenance of the Open Data Archive. This could be relevant in the future for the transformation of data from information

systems into documentary heritage. Open Data products are easy to use and manage, and they do not present any problems regarding the data privacy restrictions. Sicilia, Garcia-Barriocanal and Sanchez-Alonso, (2016) highlight that the preservation and availability of research data is a major concern as it aspects core principles of scientific practice, including repeating and contrasting experiment and sharing findings. This concern has resulted in a number of initiatives and services that offer long-term preservation of research data in a broad sense, many of them exposing data and its description in open access form. Trends in the growth, development and use of Open repositories and availability of open harvesting tools have enabled increased visibility of such repositories. These repositories are becoming significantly important for scholarly communication. They give better visibility to the research papers that they hold because of free access and downloading facilities (Jayakanth, Minj, Silva & Jagirdar, 2008). These repositories proved as blessing for developing countries as they enhanced the research capacity of such countries by providing free interchange of essential scientific knowledge combined with capacity building. Open repositories have tremendous impact as they provide timely and open access to research and scholarship, increase the potential research impact of archived publications, supporting alternative forms of journal publishing and novel forms of digital scholarship by preserving and making accessible academic digital objects, datasets, and analytic tools that exist outside of the traditional scholarly publishing system (Chan, 2004). Open data repositories as such are created and maintained to provide universal and free access to such information products in electronic format as a means of facilitating research and scholarship (Reitz, 2002). Childs, McLeod, Lomas and Cook, (2014) examined the issues and opportunities of open research data and advocated that technological development and the obligation from research-funding bodies to maintain research data and make it open for sharing and reuse are offering new challenges to the research community

which generates pressure on them to react, rather than to lead a discussion about which data is suitable for sharing and reuse, and of the processes that are required to enhance proper research that is responsive to current and future scientific and societal developments.

Kim and Lee, (2014) while analyzing the Global data repository status based on Korea, China and Japan revealed that the repository operation events operated by the government is inadequate in Asia and there are no repository operation case in learning, open data, research data and web observatory, types in Korea, China and Japan. Reichman, Jones and Schildhauer (2011) in their study on “Challenges and Opportunities of Open Data in Ecology” revealed that standardization of methods and development of robust metadata can increase data access but reproducibility of analyses is also important. The establishment of well-curated, federated data repositories will provide a means to preserve data while promoting attribution and acknowledgement of its use. This is further supported by the view that the research papers available in open access repositories get more citations than subscription based papers (Norris, Oppenheim and Rowland, 2008). Xia and Nakanishi (2012) further examined the open access availability of journal articles and their citation conditions and revealed that articles in high-ranked journals do not have a higher open access rate, and articles in lower-ranked journals have a greater increase rate of citations if they are freely accessible.

Open publication of data as such is nowadays a clear upward trend, for which it is easier to assign human and financial resources. That is why these projects should be considered as an opportunity to include the perspective of digital preservation. With the open data initiative rolling out, researchers will gain experience with making their research data open and in reusing open data in their own research (Childs, McLeod, Lomas & Cook, 2014). One reason for emerging excitement about educational data mining is the increasing availability of student learning data. These data

are coming from many sources including data from schools, like standardized tests and student and teacher background variables and videos of classroom interactions. The data can also drive improved models of student cognition, affect, and learning that can be used to improve On-line assessment and on-line learning (Koedinger, Cunningham, Skogsholm & Leber, n.d). For each discipline or scientific domain there is a particular interpretation of datasets and research data, their nature, and collection procedures and the variations in the way that data are described with metadata and the problems associated with sharing (Gomez, Mendez, & Hernandez-Perez, 2016). Open Data Repositories as such incorporate varied aspects ranging from creation, processing, modeling, linking and availability of Open data sets in different setups ranging from research institutions, educational establishments to Government agencies for supporting education, research and decision-making activities. In modern times as such Open Data repositories result in ease of sharing data with greater potential for reuse resulting in citation impact and reputation building (Johnston, 2016).

Scenario of Open Data Repositories in Different Setups

Number of Open Data Repositories has been established in different domains to support innovation, creativity, teaching/Learning activities, and research activities in specific subject areas. The availability of Open Data especially Open data for research, Open Government data has paved new means to establish credibility and accountability of funding and government agencies. Many countries are embracing the concept and have come up with number of repositories hosting open data. Few such repositories have been discussed below:

European Union Open Data Portal¹

The European Union Open Data Portal is the single point of access to a growing range of data from

the institutions and other bodies of the European Union (EU). Data are free to use and reuse for commercial or non-commercial purposes. The portal aims to promote their innovative use and unleash their economic potential. It also aims to help foster the transparency and the accountability of the institutions and other bodies of the EU. The EU Open Data Portal is managed by the Publications Office of the European Union. Implementation of the EU's open data policy is the responsibility of the Directorate-General for Communications Networks, Content and Technology of the European Commission.

The OD500 Global Network²

The OD500 Global Network is an international network of organizations that seek to study the use and impact of open data. Coordinated by the Governance Lab (GovLab) the OD500 Global Network enables participating organizations to analyze open data in their country in a manner that is both globally comparative and domestically specific. The OD500 Global Network starts from the assumption that only by mapping the use of open data within and across countries, can new approaches for understanding the economic and social impact of open government data be generated.

Open Data Commons³

Open Data Commons exists to provide legal solutions for open data and is an Open Knowledge Foundation project run by its Advisory Council and is a not-for-profit effort working for the benefit of the general open knowledge community. In March 2008 it launched the first ever open data license: the Public Domain Dedication and License (PDDL).

ArcGIS Open Data⁴

Open Data allows organizations to use the ArcGIS platform to provide the public with open access

to their authoritative data. Organizations can create a website with their own look and feel and specify Open Data groups to share specific items. The general public can use Open Data sites to search by topic or location, download data in multiple formats, and view data on an interactive map and in a table. ArcGIS Open Data currently works with data from hosted feature layers, ArcGIS Server feature services, ArcGIS Server map services, ArcGIS Server image services, CSV files, hosted tables.

Open Government Data (OGD) Platform India⁵

Open Government Data (OGD) is a platform for supporting Open Data initiative of Government of India. The portal is intended to be used by Government of India Ministries/ Departments their organizations to publish datasets, documents, services, tools and applications collected by them for public use. It intends to increase transparency in the functioning of Government and also open avenues for many more innovative uses of Government Data to give different perspective. Open Government Data Platform India has 4 (four) major modules implemented on a single Drupal instance: Data Management System (DMS), Content Management System (CMS), Visitor Relationship Management (VRM), and Communities.

Open Data for Africa⁶

The African Development Bank Group (AfDB) committed to support statistical development in Africa has a large team of researchers who focus on the production of statistical data on economic and social situations. The data produced by the institution's statistics department constitutes the background information in the Bank's flagship development publications. Besides its own publication, the AfDB also finances studies in collaboration with its partners. Through its statistics department the AfDB is contributing to the effective development of RMC statistical capacity and

systems for the provision of timely and reliable data for policy formulation, implementation and evaluation and monitoring of progress towards achieving Millennium Development Goals (MDGs) and, Poverty Reduction Strategies (PRSs). It is also responsible for developing and managing databases on economic, social and development cooperation statistics in Africa in collaboration with RMCs and regional and international agencies (ECA, IMF, OECD, UN, World Bank, etc.).

CERN Open Data Portal⁷

The CERN Open Data portal is the access point to a growing range of data produced through the research performed at CERN. It disseminates the preserved output from various research activities, including accompanying software and documentation which is needed to understand and analyze the data being shared. The portal adheres to established global standards in data preservation and Open Science: the products are shared under open licenses; they are issued with a digital object identifier (DOI) to make them citable objects in the scientific discourse. The Open Data portal focuses on the release of data that comprises data directly related to publications, simplified data formats for analysis in outreach and training exercises, reconstructed data and simulations as well as the analysis level software to allow a full scientific analysis and also covers basic raw level data and their associated software and allows access to the full potential of the experimental data.

ALICE⁸

A Large Ion Collider Experiment (ALICE) is the experiment at the Large Hadron Collider devoted to the physics of matter at infinitely small scale exploiting heavy-ion collisions. Its scientific program aims at answering a series of fundamental questions. The available primary ALICE datasets contain a limited sample of specially selected interaction events recorded from p-p and Pb-Pb collisions collected in 2010. The data format is

the ESD (event summary data) format generated by the ALICE raw data reconstruction software. These datasets are not statistically representative and therefore cannot be used to perform full fledged scientific studies. They rather serve to demonstrate the use of the ALICE analysis tools. A set of simplified datasets derived from the primary ones for use in the provided master class analyses. These data contain exclusively the information needed by the master classes and are not useful for a different purpose.

Marine Geoscience Data System⁹

The Marine Geoscience Data System (MGDS) provides a suite of tools and services for free public access to marine geoscience research data acquired throughout the global oceans and adjoining continental margins. The system evolved from projects initiated from 2003-2004 with funding from the National Science Foundation to provide data management services for the U.S. Antarctic Program (USAP), the Ridge 2000 and MARGINS programs, and for active source seismic data. The Data Systems and Services include Marine-Geo Digital Library, Community Data Portals, Antarctic Data Resources, Global Bathymetry, Visualization and Analysis Tools.

National Centers for Environmental Information (NCEI)¹⁰

NCEI is responsible for hosting and providing access to one of the most significant archives on Earth, with comprehensive oceanic, atmospheric, and geophysical data. From the depths of the ocean to the surface of the sun and from million-year-old sediment records to near real-time satellite images, NCEI is a leading authority for environmental information. NCEI continues the tradition of excellence, unmatched expertise, and trusted, authoritative data that the previous three Data Centers (the National Climatic Data Center, the National Geophysical Data Center, and the National Oceanographic Data Center) established.

The top priority during the near future is to provide full spectrum of atmospheric, oceanographic, coastal, and geophysical products and services.

eCrystals¹¹

eCrystals - Southampton is the archive for Crystal Structures generated by the Southampton Chemical Crystallography Group and the EPSRC UK National Crystallography Service. The information contained within each entry of this archive is all the fundamental and derived data resulting from a single crystal X-ray structure determination, but excluding the raw images. The results have not been externally refereed, but the information supplied should enable any reader to check the reliability and validity directly, since all the files provided are freely available for download. This eCrystals repository is made available under the Open Data Commons Attribution License.

PubChem¹²

PubChem, released in 2004, provides information on the biological activities of small molecules. PubChem is organized as three linked databases within the NCBI's Entrez information retrieval system. These are PubChem Substance, PubChem Compound, and PubChem BioAssay. PubChem also provides a fast chemical structure similarity search tool. Links from PubChem's chemical structure records to other Entrez databases provide information on biological properties. These include links to PubMed scientific literature and NCBI's protein 3D structure resource. Links to PubChem's bioassay database present the results of biological screening. Links to depositor web sites provide further information. A PubChem FTP site, Download Facility, Power User Gateway (PUG), Standardization Service, Score Matrix Service, Structure Clustering, and Deposition Gateway are also available.

Geological Society of America Data Repository¹³

The Geological Society of America established in 1888, provides access to elements that are essential to the professional growth of earth scientists at all levels of expertise and from all sectors: academic, government, business, and industry. The Geological Society of America (GSA) is a global professional society with a growing membership of more than 26,000 individuals in 115 countries. The GSA Data Repository was established in 1974. It is an open file in which authors of articles in journals can place information that supplements and expands on their article. These supplements will not appear in print but may be obtained from GSA.

ISSUES AND CHALLENGES

The major challenges facing Open Data includes issues related to availability of data created with public money as Open Data with high priority, creating an environment for openness by starting embedding Open Data in everyday's tasks resulting in shifting from policy-making process to a more evidence-based, data-powered one. Besides improving public confidence is very important by showcasing the benefits that data can bring to society in every sphere. The infrastructure improvements concerning Open Data needs to be addressed by developing Information Infrastructure at different levels (Sollazzo, 2015). The area of Open data including availability of Open data sets in different establishments through open repositories is so vast and provides conducive environment for researchers to chalk out strategies for addressing different challenges concerning open data in future.

FUTURE RESEARCH DIRECTIONS

Future of Open data will be highly influenced by the development and adaptation of open data standards, integrated portals, open data feeds, live feeds, data consistency, publishing tools, Government policies, which have power to enforce open data initiatives and goals, data literacy and demystification of open data, increased awareness, transparency, and Open source tools(Cordivano,2015).

Further Research needs to be carried on analyzing the changing dimensions in the procedures associated with the availability of open data in future. These research activities must focus on innovation, creativity and long term persuasion. Steps need to be taken in order to convince different stake holders including Government agencies, funding bodies, research institutions etc to make their data sets open for people, so that it will help establishing a more transparent and efficient system with credibility and efficiency. Open Data projects needs to be prioritized in different setups so as to explore and identify different issues concerning Open data repositories in terms of designing and management of different datasets and formats. Such activities will facilitate a more convenient and organised open research environment for addressing different issues concerning common man in future.

CONCLUSION

The benefits of Open data can be entirely realized only after incorporating technical skills among different stake holders especially in order to ascertain the quality of data made available and the associated procedures for organizing and making multiple data sets retrievable through different channels. According to IFLA trend report by 2020 governments will have realized that it takes more than rhetoric to deliver effective and transparent open government services. Currently Open Data and services especially Open Government data is mainly supply driven, when in reality it needs to

be driven by citizen demand (IFLA, 2015). There is a need for greater collaboration and cooperation among all stakeholders to solidify the gains and keep the momentum.

KEY TERMS AND DEFINITIONS

Digital Repositories: A digital repository is where digital content and assets are stored and can be searched and retrieved for later use.

Institutional Repository: An institutional repository is an online archive for collecting, preserving, and disseminating digital copies of the intellectual output of an institution, particularly a research institution.

Open Access: An unrestricted online access to peer reviewed scholarly research.

Open Data: Open data is data that can be freely used, re-used and redistributed by anyone - subject only, at most, to the requirement to attribute and share alike.

Open Government Data: Data produced or commissioned by government or government controlled entities. Data which is open as defined in the Open Definition – that is, it can be freely used, reused and redistributed by anyone.

Raiganj University, India

INTRODUCTION

Quantum Information Science (QIS) is a combination of Quantum Science (which combines Radio Physics, Condensed Physics, and Electronics) and Information Science (which combines Computer Science, Information Technology, Mathematics, Information Studies, and Documentation Studies and so on. Quantum Information Science (QIS) is actually an extension of Quantum Computing. Quantum Information Science (QIS) is mistakenly taken as Quantum Information Theory but it has several differences with this. Quantum Information Science (QIS) is mainly responsible for improved and faster acquisition, transmission and processing of information. The 20th century is marked by three monumental achievements, namely, computer science, quantum physics and information theory, which have not only stunned the civilized world but also ushered into a new world – a new paradigm of science and technology. The information technology revolution of this century was directed towards the miniaturization of electrical circuitry on silicon chips on one side, enabling performance to double every 18 months (Moore's Law) and the deepening understanding of classical information in coding, cryptography and computational complexity on the other side. Thus a new era dawned with the promise of a new design strong enough to handle the ensuing new problems. Considerable planning has already

been devoted to the challenges of designing and fabricating devices at the atomic scale using nanotechnology and quantum theory. Indeed quantum effects are being exploited to perform important, otherwise impossible information processing tasks, in addition to the creation of unbreakable codes and possibly a quantum computer to perform easily computations that would have taken millions of hours for its performance. Quantum Information Science (QIS) is actually an extension of Quantum Computing. Quantum Information Science (QIS) is mistakenly taken as Quantum Information Theory but it has several differences with this. Quantum Information Science (QIS) is mainly responsible for improved and faster acquisition, transmission and processing of information. Quantum Information Science (QIS) is actually nothing but an application and integration of Quantum Science and Information Science principles (See Figure 1). Thus Quantum Science is mainly rooted by the Quantum Physics principles and then Quantum Computing and lastly Quantum Information Science. QIS is an existing field which need an intellectuality and mentality towards achievements. Quantum Information System is the ultimate result of healthy Quantum Information Science (QIS) practice. This paper talks about Quantum Information Science (QIS); its background and origin. Possibilities of Quantum Information Science (QIS) as an academic domain and possible courses emphasize-

DOI: 10.4018/978-1-5225-2255-3.ch386

ing challenges and opportunities to introduce it in I-School or Information Science departments with specialization are explored.

BACKGROUND AND EXISTING LITERATURE

Practically, Quantum Information Science [QIS] is combination of some more subfield. The main field from Quantum Side is Quantum Physics, Quantum Mechanics, Quantum Computing and other hand the domain of Information side; which is combination of Management Science, Computer Science, Information Technology, Cognitive Science, and Operation Research and so on (Bouwmeester et al., 1997; Ahn, 2000; Paul, 2013a).

In other words, Quantum Information Science (QIS) is a combination of Quantum Science (which combines Radio Physics, Condensed Physics, Electronics) and Information Science (which combines Computer Science, Information Technology, Mathematics, Information Studies, Documentation Studies and so on, which has possibilities of healthy Information Infrastructure and speedy information access between information channels, information networks, information centre to information networks and so on (Devoret, 2013; Paul, 2013b). The wider benefit and possibilities of Quantum Information Science (QIS) attract thousands of scientists and technological experts in the field of physics and mathematics and its integration into information science. The Information Technology revolution of the past several decades has been driven by steady advances in the miniaturization of electronic circuits on silicon chips, allowing performance to double roughly every 18 months (Moore's law). Quantum Computing and Information Science mainly differs in the perspective of different uses and scope. Here physical form of information has a qualitative rather than merely quantitative bearing on how efficiently information can be processed (DiVincenzo, 2001; Paul, 2015). The economic impact of this quantum information

science (QIS) is going to be no less profound. The complexity of the economic world with its colossal information will be resolved to generate a wholly new economic paradigm. So it is important that the necessary foundation of QIS be built to provide tools to solve those problems and enable progress move forward towards more specific technical and economic growth (See Table:1 for more clarification).

OBJECTIVE AND HYPOTHESIS

The main aim and objective of the study include:

- To know about the Quantum Information Science (QIS) and its nature.
- To learn about Quantum Information Science (QIS) and its basic nature.
- To find out main advantages and engineering applications of Quantum Information Sciences.
- To find out possibilities of I-School based Quantum Information Science (QIS) programmes.
- To know about attributes and characteristics of modern Quantum Information Science (QIS).

QUANTUM INFORMATION SCIENCE [QIS] AS A DOMAIN AND GROWING INTERDISCIPLINARY NATURE

The interdisciplinary Quantum Information Science [QIS] is providing a new way into fundamentals problems related to Computing as well as Physics (NSF, 1999). Though it is important to note that, Quantum Information Science based on basic Mathematical principles and which are not new but integration is new that produce several new information mechanism powered by Quantum BITS (Leuenberger & Loss, 2001).

Quantum Information Science (QIS) is a kind of science supported by several technologies

Figure 1. Road map of establishment of quantum information sciences to learn about I-School and its emerging nature

mainly responsible for information collection, selection, organization, processing, management and dissemination with super speed and dynamic movement from one place to another within a moment (Dutt et al., 2007). Quantum Information Science (QIS) is mainly backed by optics and quantum physics; though it is now treated as a subject with far reaching implication for basic mathematical as well as physical science. Data and information are rapidly growing. Today it is very difficult to manage information thus emerging world wide both in professional practice and in academic researches. Fundamentally it is dedicated to both computer and physical science. In general Quantum Information Science (QIS) may

seem to be a combination of Quantum Science and Information Science; but practically these two include some more subjects (NSF, 1999). So ultimately Quantum Information Science (QIS) is a knowledge cluster of Computer Science, Physics, Information Studies, Management Studies, Mathematical Science, Nano-Technology. NSF, USA mentions that Quantum Information Science (QIS) is providing profound new insight into fundamental problems relating to both computation and physical science. Practically the backbone of QIS is Quantum Theory which originated nearly 80 years back and Information Science discovered nearly 70 years back (Furusawa et.al., 1998).

Table 1. Some disparities between general and Quantum Information Science

General Information Science	Quantum Information Science [QIS]
• Classical Information can be read and copied without disturbed. • In General and classical Information, it is tough or impossible to exploited perform task. • Today's general Computer will take billion of years to find the prime factor. • It is small-scale Computing depended. • To find out a particular item in general computer will take N to search.	• Information carried by a Quantum System flouts such Common sense principles. • Quantum Information Science [QIS] can be exploited to perform task. • Whereas Quantum Information Science [QIS] based computer will take just second for that. • It is large-scale Computing depended. • Where as in Quantum Information Science [QIS], Computer will take square root of N.

QIS AND TECHNOLOGICAL FEATURES

The bright future of QIS warns us about several problems in its development. We have already seen that two obvious properties of classical information are

- It can be read and copied without being disturbed.
- The state of a composite system can be fully specified by specifying the state of each of its parts.

But it is noteworthy that a quantum information system flouts such common sense principles. This implies that a quantum information system can be used to perform tasks where a classical system will fail to do (Knill et.al. 1998). Recent researches have revealed that noisy quantum devices can reliably store and process suitably encoded quantum states. Normally quantum states that arise in the intermediate stages of a quantum computation are extraordinarily fragile; but if a logical qubit is encoded not as a single physical qubit but in the form of entanglement, it becomes far more robust (NSF, 1999).

There is no doubt that the new quantum error correcting codes and fault tolerant methods will be essential for any future effort to create, maintain and manipulate intricate many-qubit quantum states (Home et.al., 2009). Hopefully the quantum information processing of moderate complexity will be soon possible in a variety of implementations, showing the prospect of a full-scale quantum computer. It is worth mentioning here that the advancement in the technology of quantum cryptography is quite satisfactory and closer to commercial realization. It can be emphatically remarked that researches in QIS will have an impact not only in nanoscale engineering and precision metrology but also in basic sciences and defence research (Imamog et. al, 1999). These imply that the future advances in researches will require the efforts of expertise

from the disciplines of mathematics, computer science, physics, chemistry, material science and engineering and information theory. Thus as one of the greatest scientific ideas of the twentieth century, QIS will set a new order of science in the twenty first century.

QIS: EMERGING APPLIED INFORMATION SCIENCE

The novelty of the quantum effects lies not merely in the quantitative but in the qualitative improvement also, otherwise impossible. This intellectually exciting field has incredible technological implications on mathematics and physics also and has started providing a wholly new language for describing the mysteries of nature and a new way of thinking about a wide variety of scientific and technological questions (Virginia, US, 2006; Maurer et.al., 2012). The new scientific tool, i.e. quantum computer is expected to play the most vital role in this transformation (See Figure 2).

INFORMATION SCHOOL VIS-A-VIS QIS AND QUANTUM COMPUTING

Information Schools are responsible for providing manpower in the field of Information and Technologies and Computing with the focus of Information. Information Schools are abbreviated as I-School and many schools and departments are make a consortium and designated as Information School (Paul et.al., 2015). There are many opportunities come with such schooling in terms of courses, research, job potentialities and interdisciplinary skills (Karski et. al., 2009).

Though it deals with some problems and challenges; this paper is talks about such preliminary aspects, emerging trends and possibilities in Indian context with international agenda. In other words, Information School or I-School is a kind of schooling concept; where several information programmes are tied up. Information Schools are

Figure 2. The interdisciplinary knowledge cluster of quantum information science and its side by side promotional affairs

next generation schools which believe not only in healthy information channel and information infrastructure building but also interaction between Information-Technology people. In many perspectives it is motivated towards information and computing application to the various parts of the society and industries. Several courses are listed in I-School; but the flagship programme is Information Science; though a new nomenclature 'Information Science and Technology' (IST) started recently for better Information and Technological solution.

Some new Information School programmes specialized in nature like Geographical Information Science, Chemical Information Science, Bio-Informatics, Music Informatics have come up by now. Thus Information Science has a long tradition of introducing interdisciplinary programmes which match with other domains like Computer Science, Chemical Science, Geography, Biology. Quantum Information Science

(QIS) may also be initiated as a full-fledged QIS Degree programme like BSc/MSc-Information Science (QIS). Quantum Information Science (QIS) initiated in I-School need joint efforts of Physical Science professionals who have expertise in Quantum Computing and Information Science professionals who believe in Technocratic Information Solutions.

QIS: EMPOWERING RAPID AND QUICK INFORMATION SYSTEM

Quantum Information Science (QIS) is mainly responsible for faster and transparent information transfer within a moment from any where and by dedicated structure powered by Quantum Computing, Quantum Physics, and Information Theory (Shor 1994). The understanding of classical type of information and data, coding, cryptography and computational complexity acquired in the preced-

ing decades has laid foundations for extension to the quantum realm (Vlastakis et.al., 2013). The development of healthy and dynamic laboratory techniques has provided the basic infrastructure for manipulation and monitoring the characteristics of single automatic, electronic and nuclear systems (Zoller et.al., 2005). These two are the main factors behind Quantum Information Science (QIS).

Quantum Information Science (QIS) is a wonderful practicing field and also a tool for building healthy and sophisticated information systems and network building (Kiraz et.al., 2004). It allows faster communication; for examples Quantum Computers can perform the search in a time proportional to the square root of N . The communication between process and within CPU and large complex computing systems may interact and transfer in a much more speedy way. Fundamentally main pillar of Digital Information Services are general computers which process classical information encoded in bits, where as Quantum Information System based computers process information encoded in Quantum bits or QBITs (Zhang et.al., 2007). Thus, Quantum Information Science affects both internal and external information systems.

QUANTUM INFORMATION SCIENCE (QIS): EMERGING FEATURES

Quantum Information Science (QIS) may be attributed as under (and also depicted in Figure 3):

- It may transfer, deliver and collect large amount of data within a moment which is tough in general Information Science Practices.
- Finding the prime factor of a number may take long time where as Quantum Information Systems based on computer may perform that task within a moment.
- Information explosion may be done in a sophisticated way with the help of Quantum Information Science (QIS).

- After Information exchange, cryptographic protocol may be devised in which privacy is ensured by the principles of fundamentals physics.
- The large scale quantum computer may boost super Quantum Technology.
- According to NSF, the main achievement is generalisation or extension of classical theory that apply when information is reprinted as a quantum static rather than in terms of classical bits.
- Quantum states are actually highly unstable and cannot be observed without being distributed.
- Virtually, QIS ensures that quantum systems of modest size are endowed with truly vast computational systems.
- The main goal of Quantum Informatics is that it is the characteristics of quantum entanglement.
- Practically, the compressibility of quantum message can be quantified.

SUBFIELDS OF QUANTUM INFORMATION SCIENCE

Quantum Information Science is mainly responsible for the speedy and transparent information transparency. Building Quantum powered Information Science practice is mainly possible with Quantum Information Science, when as it is depends on Quantum Computing. Thus, the Quantum Information Science is the longer periphery than Quantum Information Systems and lastly Quantum Computing.

Virtually, Quantum Information Science is combine with so many tools, techniques and theories which includes- Quantum Statistical Mechanism, Quantum Gravity, Quantum Computational Complexity, Quantum Communication, Quantum Cryptography, Quantum Information Processing, Conditional Quantum entropy and so on (Paul et al., 2015). However, some Quantum expert and Information expert claim and express that, apart

Figure 3. Depicted the wonderful role of quantum information sciences

from the area and field mention above some are also important fact or subject of expert Quantum Information Science, these are as follows:

- Quantum Error Connection,
- Quantum Communication Complexity,
- Quantum entanglement,
- Quantum Dense Coding,
- Shor Factoring Algorithm,
- Grover Search Algorithm,
- Classical Information Theory,
- Quantum Systems,
- Quantum Mechanism,
- Quantum Teleportation and so on.

FINDINGS

- Quantum Information Science (QIS) is a popular name in Quantum world; which includes quantum computing, quantum physics and quantum science.

- Information Science and Quantum Science makes it a professional practice and also an academic domain; earlier it was mainly treated as a practice field and as Quantum Information Systems.
- It delivers QBITS in its process in all segments rather than classical BITS.
- Practically the quantum channel and its capacity can be enhanced if the communicating parts share a super dense coding (See Table 2).

FUTURE RESEARCH POTENTIALITY AND DIRECTION

Quantum based Computer will be much more faster and speedy communication between computer networks and Information Networks. Here one Information Centre may communicate with another and one Information Centre with Information Networks and Information Systems. Quantum

Table 2. Some possible courses related to information science vis-à-vis quantum sciences in the I-schools

QIS in Information Science Context	QIS in Computer Science Context	QIS in Engineering Context
• BSc/MSc- Quantum Information Science • BS/MS- Quantum Information Science • BS/BSc/MS/MSc-Information Science (QIS) • BSc/MSc./BS/MS-Quantum Informatics	• BSc/MSc- Quantum Information Science (Computing Context) • BS/MS- Quantum Information Science (Computing Context) • BS/BSc/MS/MSc-Computer Science (QIS) • BSc/MSc./BS/MS-Computing (Quantum Informatics)	• BTech/MTech-Quantum Information Science • BE/ME-QIS • BTech/MTech/BE/ME-Computer Science, (Quantum Information Science)

Information Science (QIS) is still practiced in small processors; but it needs to be initiated in the information systems and networks. Noisy quantum channel should be removed by healthy attributes; Use of channel twice in the same direction may also send information; Research in Quantum Information Science (QIS) is needed in IT, CS, Information Science, Information Systems schools for further development of QIS. It is essential to check that Quantum key distribution provide secrecy of generating such key information. Academic Institutions need to do several things for advancement of Quantum Information Service for internet and future data Management. More over the following aspects need to take care—

- It is essential to start Quantum based Networks and Quantum based internet.
- Quantum Information Science [QIS] need to start as full-fledged programme in Indian University; however programme may be start as pass course in BSc Programmes.
- Proper funding is essential to builds Quantum based Information Infrastructure.
- Better cooperation in Computer Science, Information Science, Management Science and Physical Science may bring more interdisciplinary research.

CONCLUSION

Quantum Information Science (QIS) is fully responsible for faster as well as transparent in-

formation transfer mechanism within a moment from anywhere and by dedicated structure powered by Quantum Computing, Quantum Physics, and Information Theory. For healthy QIS practice several things need to be taken care of, out of which Quantum Searching, Quantum Communication Complexity, Quantum Error correcting codes are important ones. The aspects of Quantum are long time practiced in Atomic, Molecular and Optical Physics (AMO). Information Science and similar academic programmes need to be initiated as a full fledged academic programmes on this emerging interdisciplinary domain for building sophisticated speciality, small and large Information channels and of course Big Data or Information Infrastructure Management. Research and innovation in Quantum Information Science (QIS) is required in Informatics, Computing, Information Science, Information Systems schools and other academic units for further development of QIS as a scientific and interdisciplinary domain.

KEY TERMS AND DEFINITIONS

Computing: Computing includes designing and building hardware and software systems for a wide range of purposes; processing, structuring, and managing various kinds of information; doing scientific studies using computers; making computer systems behave intelligently; creating and using communications and entertainment media; finding and gathering information relevant to any particular purpose, and so on.

Information: Information as a concept has a diversity of meanings, from everyday usage to technical settings. Generally speaking, the concept of information is closely related to notions of constraint, communication, control, data, form, instruction, knowledge, meaning, mental stimulus, pattern, perception, and representation.

Information School: I-Schools are academic units which work for professional and academic solution of Information and Technologies. Information Schools are responsible for providing manpower in the field of Information and Technologies and Computing. I-Schools gained popularity during 1990's when internet reached the common people and other commercial ventures. It is in this time the explosion of information has lead the development of healthy information management approach. Earlier evolution of I-Schools provided such knowledge as Library Science, Communication Science, Mass-Communication, Computer Science and Information Technology.

Information Science: Information Science is actually a discipline of disciplines. It has come from the subject which deals with information, information services, information activities and digital information. So mainly from library science, archive science, documentation science, computer science it has originated; however this is not truly computer science nor library science. This is an interdisciplinary science; which is a combination of Library Science, Computer Science, Information Technology, Management Science, Operation Research and the subjects that deal with information.

Interdisciplinary: Connection between some subjects irrespective of domain and direct and indirect connection with main facet or sub field.

Quantum Computing: Computers which are run according to the power and system of Quantum Bit and only employed for faster computer operation.

Quantum Information Science: Quantum Information Science [QIS] is a new field which is responsible for faster and advance Communication powered by QBIT. Actually Quantum is the main pillar of Quantum Science. The integration of Quantum Science and Information Science may treat as Quantum Information Science [QIS]. Quantum Computer plays an important role to build healthy Quantum Information Science [QIS] practice. Today's super computer and in future computer QBIT may solve hard problem and may able in speed up communication in Computation.

Towards a General Theory of Information

Laura L. Pană

Polytechnic University of Bucharest, Romania

INTRODUCTION

Today's society and our entire epoch are often characterized as the information society, respectively the information epoch, which is the current stage of the technical era. The technology developed on information bases – Information Technology – is now exhaustively studied and further rapidly developed. Consequently, technical information is nowadays the most accessed. This article attempts to bring nearer to completeness the theory of information by analyzing social and human information, existing in various, human-like and human-made structures, processes and activities. The complex status of information is based on its double quality, namely that of an essential component of existence at all its structural levels, and that of a founding concept for many scientific, technical and philosophical disciplines. An interdisciplinary study of information is thus accomplished, by using findings from several scientific and philosophical disciplines, from Information Epistemology or Information Aesthetics to Neuroinformatics and Neurorobotics. Various information types, specific for different existential levels, such as structural information, functional information or free information will be characterized and defined, as well integrated in a general overview of the world of information. New research themes such as information values, information efficiency and information responsibility are proposed at the end of article.

BACKGROUND

Intellectual life is dominated today by information-related activities such as information generation,

information processing, evaluating, managing and using. Under these conditions, even society, as well as the whole existence could appear as a hierarchical succession of informational structures, processes and activities. This information-centered vision is supported by a series of scientific representations and philosophical outlooks. Some outstanding findings of these cognition area show, respectively argue that information is present, active and has a decisive importance at each layer and in every field of existence: in nature, society and technology. In the field of physics, various structural layers of existence are often associated with certain informational features. Sometimes the hypothesis of generation of distinct existence forms by various information contents is formulated. At other times, even a distinct kind of matter is postulated – the so named *informatter* –, characterized by some deep constitutive information sorts, such as electric charge, lepton or baryon number, charm and strangeness (Drăgănescu, pp. 52, 228, 219).

The synthetic concept of *informational energy* was coined and elaborated by means of mathematical statistics (Onicescu, pp. 4-5). The formula associated with this concept makes possible an overall characterization of the organization state of a system: when the system is completely disorganized, its informational energy is minimal, and when the states of the system tend to be reduced to a single state, its organization is total and the informational energy to maximum.

Energy, organization and information are correlated and within different technical approaches. Norbert Wiener was the first who explicitly stated that information is that what counteracts the degradation of energy as the increasing of disorder in systems, and who defined information as negative entropy or *negentropy*. In other, kindred, but more

DOI: 10.4018/978-1-5225-2255-3.ch387

nuanced approaches, as that of J. Guillaumaud, who accept only an analogy between negentropy and information, this latter is understood as *potential anti-entropy*, with the same role: that of a measure of the degree of organization of a system. Recently, datastore technologies were enriched with *active anti-entropy* applications, by which can be developed faster-growing Web-based, mobile and social networking activities, as well as cloud services, used to solve conflicts between information object replicas stored on different nodes or between concurrent client updates, and devoted to avoid physical data loss and corruption, and other events that distributed systems are built to handle. A *passive anti-entropy* system heals information object conflicts only when a read request reaches the web service from a client: any conflicts between objects that are not read by clients will go undetected. In an active anti-entropy technology, conflict resolution runs as a continuous background process, by which databases are updated in real time as new writes come in, which reduces the time that it takes to detect and repair missing or divergent replicas.

Some authors studied *information entropy* and more, its role in *social entropy*. They demonstrated that the quantity of information in a social system depends only on its complexity and dynamics (Şileţchi & Lascu, p. 19), but also that important in social entropy reducing are not only order and disorder, but also orientation or disorientation of social processes (p. 37-53); a well oriented social development can stabilize the variation of social entropy and thus can decrease the probability of crises in the society - nature interaction as in society (p. 130). Aiming to clarify some structural and operational aspects of human psychology by applying an informational research perspective, some scholars discover that information itself can be alienated in psychiatric diseases or can be alienating, when induces incertitude in individual or public mind, and indecision at social level. They use the notion of *informational conscience* (Pamfil & Ogorescu, p. 186) and propose a genetic definition of information (pp. 190-201).

By the concept of *quasi-information* R. Ruyer aims to explain and to give a content to the idea that information is inserted in matter even from the layer of elementary particles, but he also believes that the term designates everything that can be subsumed to notions such as potentiality, sense, finality, instinct or competency. He specifies that consciousness is the most important, because it alone can induce order in the world.

Other authors, such as G. Simondon, refuse to reduce the extension of information as a concept to its technical meanings, and argue that it perfectly responds simultaneously to the exigencies of quantum physics, biology and psychology or social studies, because it is linked only with energy and structure, and because of its purely operative feature (Simondon, pp. 219-220). He goes even further and – as shoved by one of his disciples – reforms the concept of information both in terms of system's meta-stability and of processes of transductivity (Bardin, p. 27).

An even larger extension of the term is proposed by J. Zeman, who studies the applications of the concept of information channel both to cosmic information flows and epistemic processes, and shows the role of information as the main negentropic factor in knowledge and learning (Zeman, 247). The concept of *informational time* and its measurement in these kinds of processes are initiated by him (p. 253).

Several scientific disciplines highlight the status of information in existence by imposing the concept of *structural information*. This notion, which also circulates in the form of “molecular information”, is used in biology and in macromolecular biochemistry, which is also called informational biochemistry. In these scientific areas have been developed methods of calculating the amount of structural information necessary to obtain complex structures (copolymers) or to measure the entropy of cell in multiplication (functional or abnormal).

Renowned representatives of Information Science and Technology are recognized for their practical approaches which are, however, in deep

accordance with the largest philosophical outlooks, specifies that "a huge number of physical things, events and actions can be described as being information" (Dertouzos, p.59). Other objects, like computing systems are able not only to use and to produce information, but also to assist humans in inaugurating new ways of knowledge (p. 173). An aspect of this forecast is illustrated by other authors, who consider that computers are powerful tools to process, to understand and to build a large variety of non-sentential representations of information, and to increase the efficiency of human reasoning (Barwise & Etchemendi, pp. 112). Such kind of technical approaches and endeavors lead to a more general concept of information that transcends the technical notion of information.

At the social level of existence the notion of information circulates with multiple significations, such as the meaning of a string of conventional signs; the content of a message; the denotation of a concept; the sense of a statement, the content of knowledge or the totality of the available elements of an expert system. From the perspective of this article, the significance of an action, the products of various activity fields, the sense of evolution of an event, and even the generative structure of a class of entities have to be added, because all these entities, structures or processes contain or even constitute information organized in various forms.

MAIN FOCUS OF THE ARTICLE

Two main objectives will be followed in this article, namely:

- To show the hierarchy of natural, social and human information structures, processes and activities;
- To integrate the various information levels, structures and features in order to ensure a valid and suitable scientific and philosophical foundation of a General Theory of Information.

The World of Information and Its Hierarchical Structure

At each level of existence can be identified forms of structuring and development, substantial contents and energetic processes that generate, incorporate or suppose information. But the existential status of information is different at distinct levels of existence and not independent of their energetic and structural properties, as Simondon stated. The physical level of existence contains information as a result of substantial processes and of energetic interactions. For the biotic level of existence is characteristic that it uses information from the environment as also its own information, with a well-determined finality. Human mind produces and processes information which is super-structured to the previous, physical and biotic levels, here information being characterized by structural and functional autonomy over previous levels. In social systems information is freed from some material constraints (physical and biotic), as well as from its subjective (psychic) determinations, at the high level intellectual activities, and is instead captured in spiritual structures in cultural forms. This is possible because:

- The social cybernetic complex of connections is open
- Social cybernetics admits feedforward and feedback type connections, not only feedback type ones
- A part of information is self-generating; people are initiators, assessors and users of this kind of information

Synthetically speaking, the physical universe contains *structural information*, the living world is organized and evolves through *functional information*, and the social system (which is an extension of natural life and the result of development in mental life) produces *free information*.

Natural living world closes information in the cybernetic circle of relationships between organism, heredity and environment. In the adaptation

process, it is the organism that changes its internal structure and functioning rather than the medium itself. In these circumstances, the information is constantly consumed, recycled and regenerated in the same forms, without this process to substantially affect the energetic or informational balance of nature. At the psychological level, the information flow is open, namely in two main directions: that determined by the purposes and results of its processing in the person's internal environment, and that opened by external (natural and cultural) possibilities. The psyche itself becomes autonomous from its own physical and biotic support, sometimes even of that social. The next level of existence, that social, is characterized by an omni-directional circulation of information. In some of its forms – mainly those highly abstract –, information may be released from all its previous bonds and, very important, a process of new information generation and even self-generation becomes possible. At this level, the object, the means and the products of activity are now becoming more and more informational.

Social Information and Its Internal Structure

Any social information has a complex internal structure, composed of at least three concentric layers.

Structural information is that which originates in the succession of levels at which information is manifested in the whole existence and which contains, at the same time, the general fund of information on the social environment. It can also be called *contextual information*, as well as *environmental* or *background information*. This type of information is included in any social information, no matter how specialized, but in concise or diffuse, implicit or tacit ways. Therefore, it cannot yet be explored and exploited by artificial information systems. Each type of social information (whether scientific, technical, political, moral or artistic) integrates, in addition to its specific content, several contextual elements and

the structural level of social information includes, in turn, and knowledge in the hard, scientific meaning, such as universal laws.

Systemic information is the specific informational content of a social unit. Such a unit may be a whole social system, a cultural area or, for instance, one of the sciences which belong to the scientific culture. The last unit of science is theory, because an acquaintance has no meaning and cannot be true than under or in terms of a theory. It can be also part of an informational unit by excellence, such as a sentence, a theorem, or a specialized database. Systemic information can be called *specific information* too, because contains information about the object, means and products of activity in well defined social fields;

- It is the one involved in the production of novelty in the social system.
- This category of information is systematized in disciplines and developed through coherent research programs: scientific, technical, philosophical etc.
- If, at the first social information level, the main function of information is that of prerequisite for knowledge, at the second level it is that of foundation for social action, be it theoretical or practical.

Active information is that which “puts to work” specific information, and at this level, structural and specific scientific information are translated into practical rules, working methods and appropriate techniques for different activity fields. This type of information can also be called *generative information*, for the following major reasons:

1. Contains in an unmediated manner the generative structure on which relies the production of new social structures;
2. Represents and permanently reproduces the deep intellectual structure of humankind itself;
3. Constitutes a condition of manifestation of his creative faculty;

4. It is the information that can be considered the core of individual creativity, and can therefore be named *nuclear information*;
5. A well informed and cultivated person, more exactly, the personality - the only creative social entity - becomes the source of the new and significant social information.

The active, generative information can, in turn, to be organized in various ways.

Information-Shift Phenomena of the Information Age

Several changes which shape the features of the information structure of present society can be here only concisely outlined and described.

- **The Wrap-Up Phenomenon of Social Information:** Each unit of social information is composed of concentric information strata; in our times a few meaningful restructuring phenomena occur within the information clew:
 - The mental functions, operations and processes, as well as the conceptual structures which constitute the generative structure of the entire cognitive and creative activity, are now modeled and simulated by the computer, that changes its own status of intelligence amplifier and takes over or even change a few cognitive structures, functions and activities;
 - Second information stratum constitutes the most consistent part of cognitive information, that becomes, almost entirely, scientific and technical information; it is composed of
 - The results of various specific creativity fields, together with
 - The appropriate cognitive instruments and skills, languages and cognitive styles, which are also changed and adapted to

new knowledge work types and environments;

- The exterior stratum now becomes, by contrary, more and more inconsistent, even if it has, in this context, a comparable role with that of atmosphere among other geo-spheres. It provides two types of information, namely:
 - Data, representations and beliefs about nature, civilization and culture;
 - Information about the socio-technical system, mainly about information structuring, processing and transmitting systems, techniques and skills.
- **Present Changes at Various Levels of Social Information:**
 - Transition phenomena from systemic information to general information that has as a result a phenomenon of informational “subduction” and finally, the rising of the general level of social information;
 - Processes of transformation from general information to active information, often manifested as “melting” and dissipation of the pyramid of knowledge;
 - A constant deepening of general information and the corresponding hypertrophy of specific information, a process which results in the building of a double pyramid, with the inversed pyramid of specific information in an impossible equilibrium on the pick of the pyramid of general information.

This analytic but concise presentation of the variety of information forms, of their contemporary hierarchy and of their present changes allows the building of an integrative perspective and of a general overview on information, able to show the totality of structural levels at which is or can

be organized the amount and the variety of information which is generated, stored, processed and used worldwide today.

SOLUTIONS AND RECOMMENDATIONS

Taking the envisaged spectrum of scientific results as acquired bases, and the above presented and synthesized original findings as well-founded knowledge, a number of explanatory definitions of information can be formulated here, from more factual to more general ones.

Information is the generative structure by which the world is self-organized, by using the existing content and the specific properties of its levels, and by taking shapes selected from the set of inherent possibilities of these levels. (1)

Information appears, from this perspective, as an intern-structural component of the whole existence. More specifically said, the world is structured through various kinds of components, properties, relationships, functions and products, some of which being informational. This statement may result in a new design of the concept.

Information is an irreducible manifestation of the entire hierarchy of existence. (2)

Given the multiple and active relation of information with the nature, structure, functions, relations and interactions of systems, as well as with the sense of evolution of systems which compose the whole existence, a new conceptual determination of information follows.

Information belongs to the very essence of existence. (3)

A more detailed analysis leads to another ontological definition.

Information is the set of internal, specific and stable properties of entities and processes, both material and energetic. (4)

Thus, information is not only belonging to the essence of existence, as shown in (3).

Information is the essence of existence. (5)

But the most promising hypothesis on the nature of information may be derived from N. Wiener's conclusion that information is neither matter none energy.

This thesis allows the possibility to see reality as including three basic forms of existence: matter, energy and information.

Therefore, another even more powerful definition of information can be considered here.

Information is a fundamental form of existence, just like matter and energy. (6)

Information can be interpreted quantitatively as a physical entity, such as mass and energy, but it is qualitatively different from them, because it refers always to internal, specific and stable features of a particular system or of an organization layer of systems. As shown, it is just the opposite of physical entropy, is negative or anti-entropy.

Information differs from both matter and energy, but exists beside and together with them.

Very important for the aim to build a General Theory of Information is that an information status may be acquired both by matter and energy, under certain conditions and – at the social level especially - in the presence of some appropriate devices.

At conceptual level, matter, energy and information may be mutually defined. Matter is named “slowed energy” by a few physicists, while energy may be seen as wavy matter. Information is matter reduced to its deepest internal structure, while reported to energy information can be seen as a both structure and evolution generating power.

A distinction made between two kindred concepts - informativeness and informativity – is also useful to explain the very status of information within existence.

Informativeness regards a human or artificial information source or product (a sentence or a diagram, a device or a system that processes signals) and shows the information potentiality of the source. Barwise and Etchmendy specified (1998) that the concept expresses the amount of information in a signal, that can be measured by the number of possibilities eliminated by that signal. L. Floridi studied the *degree of informativeness* (Floridi, 2003, p. 54), as the possibility to calculate it (p. 55) and established that the average informativeness of a string of symbols depends on the probability of occurrence of each symbol. Thus, more possibilities of occurrence eliminated, the more information can be extracted.

Informativity is a concept which can be applied to a larger category of entities or processes and - from the perspective of this work, as on the basis of the already gathered arguments - even to the totality of existing entities. Informativity is a fundamental property of existence, just like dynamism or connectivity, structurality and infinity. Informativity consists of the capacity of universe, as well as of each its component, of integrating, of structuring and developing, of transmitting and using information. Thus, each entity or process and product can be both informed and informer, informing and receiving information.

The path towards a General Theory of Information is also paved by contributions of the philosopher M. Bense, who also studied mathematics and physics, and formulated the *co-reality* hypothesis, within his aesthetic theory, which passed from metaphysical aesthetics to mathematical aesthetics and then to informational aesthetics. Bense also coined the concept of *aesthetic information* but, more important, he made a generalization of the concept of “aesthetic state”, applied both to natural, cultural and technical objects, any object of reality being both a support for sign (vehicle of

information) and a sign. In his view, information is not an aspect of reality, none one of its properties or functions, but is another reality.

A number of other ways to study information – mathematical and technical - also arrive at meaningful generalizations. Any event can be treated with informational tools and, in conclusion, reality itself, in its entirety, consists of various information states and their changes, i.e. events, and has an informational nature or simply, is information.

Brain itself, as well as the whole string of mental processes and products it supports can be studied and represented as different-order information states (Pană, 2016). A series of scientific and philosophical disciplines explore these processes and products from an informational perspective. Neuroinformatics studies brain both as a biotic system structured from many kind of specific cells with their own genetic information, and under its wave aspect, as in the Brit Brain Wave Project (2011-2012), and with not only theoretical, but also practical purposes: NASA invests in Neurorobotics to create Robonauts or even more, spatial robots, which will be send as light beams that will contain all the necessary information to be materialized where they will work.

Information Epistemology, where the terms *information permeability* and *information competency* were coined, is now continued with means of Information Science and Technology, e. g. by studying how “knowledge objects” are update by various, upward, horizontal or downward informational permeability processes, which have a specific role in information propagation within society (Borgo & Pozza, pp. 99-100).

Experimentally validated sets of information competence are elaborated and used now in universities and described in collaborative works such as (Pinto et al.). These tests were also adapted to self-assess and report perceptions of information competence along with intergroup experiments, in which variables such as text comprehension, interest, quality and credibility were evaluated (pp. 440, 446). Information competency has more

than individual and special, educational meanings and roles, as showed in (Pană, 2000, pp. 167-168). The term covers:

- The capability of a person or of a system to search, acquire and store information,
- The ability of efficiently use the available information, and mainly,
- The human power to generate new information.

Other, social aspects of information competence are to:

- Gather, select, order and to update information with social content and importance;
- Structure social information in order to meet the specific needs of various decision authorities;
- Keep social information ready to be used;
- Distribute it at all institutional levels with economic, social or educational competences, in order to ensure an effective use of the totality of available social information.

An information continuum, which roams through every field of existence and which connect all its structural layers may be distinguished. The social space-time continuum makes evident the same information continuum, but with a few particularities, such as:

1. A differentiated request and use of information flows and reserves, which may be excessive, sufficient or even deficient, in distinct moment and various situations;
2. Not only the quantity of information that circulates in specific fields and channels, but also the presence of social opportunities for using or generating new information is also important;
3. The degree in which information is involved in social processes and is, thus, productive, has large variations;

4. Socialization of information exceeds its technical, economic and administrative using: both humans and societies are information-oriented;
5. Technological responsibility is here extended and now even deepened by a new kind of responsibility - *informational responsibility*;
6. A special type of social efficiency is now emerging – *informational efficiency* – in the more and more large and dense field of information activities.

The present society is characterized by information thinking, information action, information humankind as well as by information machine and, mainly in this, *stricto sensu*, it can be taken as an information society.

FUTURE RESEARCH DIRECTIONS

- To deepen Information Science and Information Technology by studying technical information and its specificity. Several ways to do this are:
 - To discuss with new theoretical instruments the present meanings and relationships between concepts such as data, information, cognition, action and responsibility, in order to re-evaluate the results of earlier debates, animated by scholars such as J. P. Dupuy, Sybille Krämer, J. Mingers or G. Rapohl;
 - To envisage technical information as part of social information, as well as its formatting social role, by studying new social realities such as informational thinking, informational action, informational machine, informational man and informational society;
- To continue exploring human structures and processes such as brain, mind, cognition, consciousness and creation, from an informational perspective;

- To extend the study devoted to the world of information in order to develop an authentic information culture;
- To study the constitutive entities of the information culture: *information values*.

CONCLUSION

A General Theory of Information is now both necessary and possible. Its building is even more feasible than a general theory of physical particles, of physical interactions or of the main physical forces, which are constantly followed but still unrealized goals of scientific community. These theoretical constructs are hard to be accomplished because human scholars aim to produce universal truths although their findings are acquired in a “corner” of the universe. By contrary, humans are in the center of the information world and more, human brain and therefore humankind, are the most complex and advanced information systems. However, to build a General Theory of Information, a series of prerequisites are still needed, ones that are consisting not necessarily of a newer or greater amount of information, but of new approaches, interdisciplinary and integrative inquiries, and maybe mainly of a more advanced reflection capability.

KEY TERMS AND DEFINITIONS

Free Information: An information variety which is produced in society in high level intellectual activities, and which is able even of self-generation, under specific human or technical conditions.

Information: Is a basic existence form, the third one after matter and energy.

Informativity: A fundamental property of the whole existence, beside dynamism and connectivity, structurality and infinity; it consists of the capacity of universe, as well as of each its component of integrating, of structuring and developing, of transmitting and using information.

Social Information: Is a multileveled, multifunctional and multi-directed information flow and net.

Structural Information: A kind of information present at all existential levels – nature, society, technology and human mind.

Structurality: An objective, universal and essential feature of existence which consists of its capacity of self-organizing in more and more complex systems and to constitute an infinite succession of relatively homogenous and relatively stable organizing levels.

Systemic Information: Is an information sort characteristic to various social units, from types of civilization, cultural area and social systems, to educational systems and scientific disciplines.

Information Retrieval

Analysis and Assessment of Cross–Language Question Answering Systems

Juncal Gutiérrez-Artacho

María-Dolores Olvera-Lobo
University of Granada, Spain

INTRODUCTION

Within the sphere of the Web, the overload of information is more notable than in other contexts. Thus, too often, on planning a search with tools from the Web (search engines, directories, or meta-search engines), the number of web pages found proves excessive and not all of them are relevant or useful for the objectives of the user.

Cross-language information retrieval (CLIR) is an active sub-domain of Information Retrieval (IR). Like IR, CLIR is centered upon the search for documents, reconciling queries and documents which are written in different languages. Cross-lingual information access covers a wide range of tasks that enable users to access information in languages other than their own, including IR, Question Answering, information extraction and summarization. CLIR enables users to find information in languages they do not know, but CLIR search results are not immediately useful because a separate translation techniques must be applied before the user can read the results. This type of systems has opened a new research field that examines the most effective methods for IR and investigates which resources are required for a correct translation.

Question answering systems (QAS) are presented as an alternative to the traditional Information Retrieval (IR) systems, seeking to offer precise and understandable answers to factual questions instead of showing the user a list of documents related to a given search (Jackson

and Schilder, 2005). The functioning of QAS is based on short-answer models (Blair-Goldensohn et al., 2004), and the main advantage that it offers is that the user does not have to consult complete documents to collect the information needed, as the system provides the correct answer in the form of a number, a noun, a short phrase, or a brief fragment of text.

In relation to the types of QAS, the present work focuses on the analysis and assessment of multilingual and cross-language QAS. These systems need to include some type of linguistic translation resource, tool, or technique for the proper retrieval of the result, since the QAS can retrieve the answer from a collection of documents written in languages differing from the one in which the question is formulated. Given that the QAS is presented as a substantial advance in the improvement of IR (Kolomiyets and Moens, 2011), it becomes necessary to determine its effectiveness for the final user. With this aim, 7 studies were undertaken to evaluate: a) in the first two, the linguistic resources and tools used in these systems for multilingual retrieval (Research 1; Research 2); and b) the performance and quality of the answers of the main monolingual and multilingual QA of general domain and specialized domain in the Web (QuALiM, SEMOTE, START, TrueKnowledge, and HONqa) in response to different types of questions (of definition, of facts, and of lists) and subjects (e.g. art, literature, biology, medicine, names, history, economy, or sports), so that different evaluation means can

be applied (Research 3, Research 4, Research 5, Research 6, Research 7).

BACKGROUND

In the field of CLIR tools are being created that can greatly assist specialists in their work; as well as helping other users find a wide variety of information. These tools are evolving but several years of study and research are still needed to improve implementations. One of the main difficulties facing these tools is the task of translating queries made by users and the documentary sources found in response (Diekema, 2003). Given the current expansion in research, development, and the creation of CLIR systems, it was considered worthwhile analysing and evaluating the resources used by one type of these systems: multi-lingual QAS.

Frequently, a keyword query entered into a web search tool (search engine or meta-search engine) to satisfy a user's information need, provides too many result pages – many of which are useless or irrelevant to the user. In effect, modern IR systems allow us to locate documents that might have the associated information, but the majority of them leave it to the user to extract the useful information from an ordered list (Dwivedi & Singh, 2013). In contrast to the IR scenario, a QAS processes questions formulated into Natural Language instead of keyword based queries, and retrieves answers instead of documents (Peñas et al., 2012). Therefore, the usefulness of these types of systems for quickly and effectively finding spe-

cialized information has been widely recognized (Diekema et al., 2004).

While the development of QAS represents progress, the systems nevertheless suffer restrictions. Many were only developed as prototypes, or demonstration versions, and few were marketed. Some researchers have designed and created systems that were presented and discussed at various forums and conferences. However, because the usefulness of the systems was limited to very specific contexts, or because of problems of implementation, only a few of these systems were later developed for end users.

These circumstances have fuelled academic interest in CLIR, and the techniques of natural language processing. This interest led to many conferences dealing exclusively, or partially, with CLIR – such as TREC, the Cross-Language Evaluation Forum (CLEF), the NII Text Collection for IR Systems (NTSIR), the Language Resources and Evaluation Conference (LREC), among others. However, research on CLIR, which mostly began in 1996, has not led to commercial success and so dissemination was limited.

METHODOLOGY

For the purposes of in-depth analysis of QAS, a series of studies has been proposed which are gathered together in seven research articles published in international magazines with peer review and a chapter in a book. The following table provides a summary of the aspects addressed in the analysis performed.

Table 1. Summary table of the contents of the publications

A1: Analysis Oriented at Resources and Linguistic Tools in Multilingual QAS		
Research 1: Analysis of the linguistic resources used in CLEF		Research 2: General analysis of linguistic resources used in QAS
A2: Evaluation Oriented at the System		
Research 3: Identification and analysis of the evaluation measures used for the testing of QAS		
Research 4: Evaluation of QAS as efficient sources of terminological information.	Research 5: Evaluation of general domain QAS against those of specialist domain in the biomedical field.	Research 6: Evaluation of the efficacy of the functioning of general domain QAS.
Research 7: Final evaluation. The objective and subjective evaluation of the multilingual search for answers		

The first analysis (A1) consists of two studies focusing on the analysis and evaluation of the resources and linguistic tools used by multilingual QAS to solve the problem of translation. The first study centres exclusively on the publications presented at *Conference and Labs of Evaluation Forum*, as it is the conference that has most committed itself to this type of system, every year holding a *track* dedicated to this area. The second study extends to a number of contributions made in the field, analysing all the conferences, congresses and forums in the area of IR.

The second analysis (A2), called 'Evaluation oriented at the system', consists of three related objectives. Firstly, all the measures used in the *QA tracks* of the three main QAS evaluation campaigns: *Text Retrieval Conference (TREC)*, *Conference and Labs of Evaluation Forum (CLEF)* and *NTCIR (research 3) Conference*. The different specific *tasks* or *labs* created in each *QA track* have been identified, as have the type of evaluation questions and the evaluation measures used in the different competitions analysed. This first part of the analysis has been essential in order to detect the most recurrent evaluation measures.

The second part of this evaluation consists of three tests (*research 4*, *research 5* and *research 6*) where there is analysis, evaluation and comparison of the monolingual and multilingual QAS, general and specialist, available on the Web; and also of a fourth analysis, where a final evaluation has been made (*research 7*), which brings together all the preceding objectives. This consists of an objective evaluation, as it analyses and evaluates the answers offered by the multilingual QAS, and a subjective evaluation, as it incorporates the results of the earlier studies and analyses the sources of information from which the answers have been taken.

This series of tests, with a perspective as much quantitative as qualitative, has allowed for the evaluation of the functioning and quality of the monolingual and multilingual QAS available on the Web, as well as those which, although developed, have not yet been made available to end users.

RESULTS

First Analysis

The basic premises that have guided this analysis were: a) the use of QAS enables research in multiple languages, provides faster responses, and increases the likelihood of the user obtaining the right answer; b) cross-language QAS try to overcome the language barrier, which is one of the most maxim in the IR field; c) the linguistic tools that most affect efficiency in the field of cross-language QAS must be identified.

This analysis is primarily intended as a general purpose analysis and aims to encompass translation in the study of cross-language QAS. The second general aim is to identify and analyse the linguistic resources and tools found in these systems. Specific objectives include identifying the main types of language resources and tools useful in the multi-lingual IR processes associated with cross-language QAS, and establishing how much use is made of these tools by cross-language QAS.

A semi-empirical methodology was adopted for the two researches and the collection of data about the tools and linguistic resources employed by these systems; as well as their use and implementation. The first stage of the studies focused on identifying the major conferences, meetings, and forums that address cross-language QAS. The aim was to find, analyze, and compare the different types of linguistic resources. Although a growing number of IR conference are held each year, not all include a section devoted exclusively to QAS, and even fewer tackle multi-lingual aspects. In the first research some 165 papers published between 2000 and 2008 at the above, and other, conferences were reviewed, and 315 papers research published between 2000 and 2011 at the above in the second. Over 75% of the published articles were presented at CLEF.

Five main types of linguistic resources used in multi-lingual QA systems were identified following an analysis of the literature. The main resource types were databases, corpora, dictionaries, ontologies, and thesauri. These resources and tools,

along with their various types and subtypes, do not run in the same way and use differing methods of processing information. Sometimes, a single resource was insufficient and several resources were used together to achieve better results.

We found that automatic translators remain the most popular option, despite the fact that the authors of the papers recognize the resulting problems of ambiguity. It is the low computational cost and ease of storage that accounts for the popularity of automatic translation among developers. In our opinion, this tool can be adequate for IR when combined with other resources. However, there have been some changes in the use and incorporation of these resources and tools. The three most popular traditional resources (automatic translators, dictionaries, and corpora) are gradually leaving a widening gap for others — such as ontologies and the free encyclopaedia Wikipedia. In addition, other approaches such as computational grammars are slowly attracting more researchers who are experienced in handling the results they produce. This data suggests that we may see unexpected changes in the future and this area deserves to be studied and evaluated in future research.

Second Analysis

The evaluation of QAS is a major research area that needs attention, especially with the emergence of domain-oriented question answering systems based on natural language understanding and reasoning (Sing et al., 2005). We can find different analyses referring to the evaluation of QA systems, such as those focusing on the evaluation of QA systems on the Web (Athenikos & Han, 2010; Cruchet et al., 2009; Fahmi, 2009; Jacquemart & Zweigenbaum, 2003; Lee et al., 2006; Olvera-Lobo & Gutiérrez-Artacho, 2010, 2011a, 2011b, 2011c, 2012, 2013a, 2013b, 2014, 2015; Terol et al., 2007; Yu et al., 2007; Zweigenbaum, 2005, 2009) or in some of the international evaluation forums (Peñas et al., 2012; Forner et al., 2010).

The third research is a brief review of the TREC, CLEF and NTCIR Conferences from the QA perspective. We present a historical overview of 15 years of QA evaluation tracks using the method of systematic review. We have examined identified the different tasks or specific labs created in each QA track, the types of evaluation question used, as well as the evaluation measures used in the different competitions analyzed. Of the conferences, it is CLEF that has applied the greater variety of types of test question (factoid, definition, list, causal, yes/no, amongst others). NTCIR, held on 13 occasions, is the conference which has made use of a greater number of different evaluation measures. Accuracy, precision and recall have been the three most used evaluation measures in the three campaigns.

After having identified the different evaluation measures proposed in the tasks to be used in the evaluation of the QA systems, it can be seen that around 50 evaluation measures of very different types have been used. It is the traditional measures of IR (precision, recall, accuracy) which continue to be the most used. However, we find variances in the different tracks since the measures are applied so that they are suited best to the particularities of each task and the evaluation needs of each competition. Another of the commonly used measures is MRR (Mean Reciprocal Rank) proposed by TREC, which is very useful for the evaluation of QA systems as it makes it possible to take into account all the answers retrieved by the system and to assign it a reciprocal value in accordance with the ranking of the system. The traditional F-measure, which combines with recall and precision, is also prominent.

In the fourth, fifth and sixth researches, we took a sample of 150-200 definitional questions about different medical from the webpage WebMD, and a sample of 500 questions of different types (definitional, factoid, yes/no and list) about different issues from CLEF and TREC forum. Results obtained for the six systems analysed (START, MedQA, TrueKnowledge, SEMOTE, QuALiM and HONqa) allowed us to evaluate their effective-

ness and their use of different information sources. To evaluate the effectiveness of the systems, we applied several measures of evaluation: MRR, FHS (First Hit Success), TRR (Total Reciprocal Rank), MAP (Mean Average Precision), AveP (Average Precision), Precision and Recall.

Despite certain limitations on the part of both systems (a lack of accessibility for the general public, and insufficient development in some specific areas), we were able to confirm that these QAS are very useful in the retrieval of valid information, with responses from both proving coherent and precise to an acceptable degree. They also help in understanding the information collected and are set to become one of the key tools available to index and organise specialised information. In addition, these approaches together with others are slowly attracting more researchers who are experienced in handling the results they produce. These data suggest that we may see unexpected changes in the future and this area deserves to be studied and evaluated in future research.

Finally, in the seventh research, an analysis has been made of the results offered by the QA multilingual biomedical system HONqa, available in the Web. The study has used a set of 120 biomedical definitional questions (What is...?), taken from the medical website WebMD, which were formulated in English, French, and Italian. The answers have been analysed using a series of specific measures (MRR, TRR, FHS, precision, recall, MAP), as well as sources used to get the responses. The study

confirms that for all the languages analysed the functioning effectiveness needs to be improved, although in the multilingual context analysed the questions in the English language achieve better results for retrieving definitional information than in French and Italian. This may be because the information sources from which the answers are elicited are more numerous in English and have a more appropriate structure for this purpose than in the other languages studied.

The open-domain systems retrieved fewer answers than the restricted-domain systems, with START in last place followed closely by QuALim. In the restricted-domain QA systems, the results increased substantially, especially in the case of HONqa, while MedQA was slightly better than the open-domain systems. The correct answers were present to the greatest degree in START, open-domain system. In relation to the inexact answers, the QA system with the lowest average was HONqa (7.99%). The remaining QA systems offered similar averages. Finally, the incorrect answers were also lower in the open-domain systems, like START.

The value obtained by applying the MRR and FHS evaluation measures indicates that MedQA best ranks answers, as the first correct answer appears at the top of the list of results. This is significant in that the system does not use any sort of rank algorithm to carry out this process but rather it always recurs to the same order of answers based on the knowledge source. FHS

Table 2. Summary of each research in the evaluation oriented at the system

Evaluation Oriented at the System		
Research 3: Identification and analysis of the evaluation measures used for the testing of QAS		
Research 4: Evaluation of QAS as efficient sources of terminological information. QAS: START and MedQA Evaluation measures: MRR, TRR, FHS and precision	Research 5: Evaluation of general domain QAS against those of specialist domain in the biomedical field. QAS: START, QuALim, MedQA and HONqa Evaluation measures: MRR, TRR, FHS and precision	Research 6: Evaluation of the efficacy of the functioning of general domain QAS. QAS: START, QuALim, SEMOTE and TrueKnowledge Evaluation measures: MRR, TRR, FHS, precision, AveP and MAP
Research 7: Final evaluation. The objective and subjective evaluation of the multilingual search for answers QAS: START, QuALim, MedQA and HONqa Evaluation measures: MRR, TRR, FHS, precision, recall, MAP and AveP		

turns out to be a very relevant metric, as users often tend to focus on the first answer obtained, disregarding the rest. The other restricted-domain QA system, HONqa, is in the opposite situation, as it offers the lowest FHS value but has the second highest average in MRR. The precision of the two open-domain QA systems is quite similar, and there is not a great deal of difference between the two metrics, which is explained by the fact that the answers retrieved for each question usually fluctuate from one to three.

However, the TRR metric is greater in the restricted-domain systems as it considers the value of each correct answer based on its position in the list of results. Naturally, this value increases when more results are offered.

However, the recall shows us that the two open-domain QA systems are less exhaustive than the restricted-domain ones. So START presents a recall value of 21.87% and an average of retrieved answers of 1.6, and the values of QuALiM are 22.13%, referring to the recall measure, and an average of three retrieved answers.

Finally, the correlation between the metrics used in this study shows a significant correlation between TRR and MRR because they focus on similar characteristics of the answers retrieved by QA systems.

FUTURE RESEARCH DIRECTIONS

Despite the numerous advantages that these new IR systems offer, the underlying restrictions of the QAS limited their immediate popularity, as well as their general implementation on the web. We believe that this line of investigation may also be continued by extending the analysis and evaluation of the new multilingual systems that have appeared in recent years. As regards Cross-Lingual Information Retrieval in the Translation discipline, it is of considerable interest for the development of cross-lingual resources and tools. Carrying out interdisciplinary and transdisciplinary studies in IR and translation must be continued in order to enrich this area of research.

CONCLUSION

The conclusions obtained from the two evaluations carried out were as follows:

1. In the first analysis, although the first study shows a trend towards the most traditionally popular tools, the second study reflects a little change towards new and more versatile resources. In general, the majority of the resources grow in popularity, which presents a promising future. Although the combination of various resources needs to be studied better, the analysis suggests that, in order to achieve full coverage, the use of two or more resources are necessary for translation, especially for certain language pairs.
2. In the second analysis, although the different forums cannot be compared with each other since each has its own history, tradition and objectives, the third study shows a new scenario which is an excellent testing ground for the relevance of using traditional methods of evaluation, and for proposing and adapting new measures appropriate for this environment.

The system evaluation studies show that the six QAS can be considered good resources for general and specialist information retrieval. As regards the multilingual aspect, the answer retrieval still has a long way to go to reach the levels of efficacy of the general retrieval systems. These systems must improve in terms of information retrieval and presentation of answers.

KEY TERMS AND DEFINITIONS

CLIR: CLIR (*cross-lingual information retrieval*) involves at least two languages in this process.

Cross-Language QAS: The Cross-Lingual Question Answering systems are a set of coordinated monolingual systems in which each extracts responses from a collection of separate monolingual documents.

Evaluation Measures: Many different measures for evaluating the performance of information retrieval systems have been proposed. The evaluation of QA systems has been carried out by the traditional evaluation measures based on the relevance (precision and MAP), and also, by other specific measures like MRR, TRR and FHS.

FHS: First Hit Success (FHS) assigns a value of 1 if the first answer offered is correct, and a value of 0 if it is not (thus it considers only the answer that appears in the first place on the list of results).

Information Retrieval: Fully automatic process that responds to a user query by examining a collection of documents and returning a sorted document list that should be relevant to the user requirements as expressed in the query.

MAP: Mean Average Precision: For systems that return a ranked sequence of documents, it is desirable also to consider the order in which the returned documents are presented. MAP measures the Average Precision of a set of queries for which the answers are arranged by relevance.

MRR: Mean Reciprocal Rank (MRR) assigns the inverse value of the position in which the correct answer is found (1 if the first, $\frac{1}{2}$ if the second, $\frac{1}{4}$ if the fourth, and so on), or zero if there is no correct response. This measure considers only the first correct response shown on the list of results offered by the system, and the final value is the average of the values found for each question. MRR assigns a high value to the responses that were in the highest classification positions.

Question Answering Systems: As an alternative to traditional IR systems they give correct and understandable answers to factual questions – rather than just offering a list of documents related to the search.

Translation: The process of translating words or text from one language into another.

TRR: Total Reciprocal Rank (TRR) is useful for evaluating the existence of several correct responses offered by a system to the same query. In these cases, it is not sufficient to consider only the first correct response in the evaluations, and thus TRR takes all of them into account and assigns a weight to each answer according to its position in the list of results retrieved. Thus, if the second and fourth answers on the list of results are correct for a question, the TRR value would be $\frac{1}{2} + \frac{1}{4} = \frac{3}{4}$.

Challenges in Collecting Qualitative Data for Information Systems Studies

Tiko Iyamu

Cape Peninsula University of Technology, South Africa

Irja Naambo Shaanika

Namibia University of Science and Technology, Namibia

INTRODUCTION

In research, problem is not necessarily something that is broken, but phenomenon which require further or an in-depth investigation for a fresh perspective. Thus, every research necessitates a problem statement, goal and objectives, which determines the data collection methods. The data type can be either quantitative or qualitative. According to Seidman (2012), depending on the objectives of the study, either the qualitative or quantitative research methods are selected for data collection. However, both methods can be selected, which is referred to as a mixed method (Barbour 2013; Silverman 2013).

The choice of research methods is critical in that they influences the way in which data is collected and analysed. According to Myers and Avison (2002,p70), qualitative research methods were developed in the social sciences to enable researchers to study social and cultural phenomena. The primary purpose of qualitative research is to understand a phenomenon as it is seen by respondents within a period and space. This is achieved by studying the respondents in their natural environments. Yin (2010) takes the argument further and states that the events and ideas emerging from qualitative research can represent the meanings given to real life events by the people who live them, not the values, perceptions or meanings held by researchers. However, the meaning which individuals and groups give or associate to events of Information systems

and technologies (IS/IT) has never been easy for researchers to understand.

BACKGROUND

IS/IT are used to support and enable organisations' operations including strategic intents. IS/IT does not operate in vacuum, but in socially constructed environments. According to Iyamu, Sekgweleo and Mkhmazi (2014), IS is not only made up of technology by its self, it also includes human and non-human actors, making it more complex than often seen from afar. The multifaceted nature of information systems does not make studies in the field easier. Also, there is a great diversity in the research methods and approaches that are employed in IS studies (Myers & Avison, 2002). However, it is believed that qualitative research methods are being used increasingly in evaluation of IS/IT studies (Kaplan & Maxwell, 2005). Qualitative methods are often employed to study the socio-technical aspects of IS, and to help researchers including postgraduate students to draw conclusions on why things happen in the way that they do (Iyamu, 2010).

Theoretically, many postgraduate students in the field of IS are knowledgeable about data collection methods, techniques and approaches. However, in practice, there are numerous challenges in how their knowledge is applied (Hen-nink, Hutter & Ajay, 2011). This has led to many students not able to complete their studies, or take

longer to do so. This is the primary motivation of this study. This chapter discusses hands-on experience, reveals pitfalls and challenges in collecting qualitative data, using semi-structured technique, towards achieving research objectives. The remainder of this article is divided into six main parts. The first and second covers literature review. The third discusses the processes that are involved in data collection. The fourth presents the major challenges that are encountered when the semi-structured method is employed in data collection. Future research is stated in the sixth part. Finally, a conclusion is drawn.

RESEARCH QUALITATIVE DATA

The qualitative research methods are considered to be most appropriate for studying the social world. Hence the type of data is critical, from the perspectives of actors' intentional and unintentional acts. Erickson (2012) emphasises that the essential purposes of qualitative research methods are to document in detail, the conduct of everyday events, and to identify the meanings according to those who participate and witness them. According to Kaplan and Maxwell (2005), qualitative methods are primarily inductive. In the beginning the focus is on a specific phenomena and based on that, the findings can be generalised. Thus, qualitative methods does not allow definition of variables before the research process begins (Carla, 2013), but rather researchers studies phenomena without predictions and assumptions of outcome, making data collection critical.

The qualitative data enables researchers to examine and understand the relationship and interactions between human and non-human factors, which do not necessarily depend on quantity. Stahl (2013) states that understanding of socio-technical phenomena aims to lead to better or better usage of systems. In the same context, Erickson (2012) explains that the qualitative data helps to find and examine: (1) detailed information about implementation, actors and processes; (2) identify the nuances of subjective understanding that motivate

various participants in a setting; and (3) identify and understand change over time.

Qualitative data is connected to research methods, such as case study, ethnography and action research. Myers and Avison (2002) discusses the case study, ethnography, action research and grounded theory as qualitative research methods that can be used in IS. The options broaden, and instill depth in IS studies in the use of qualitative research methods. According to Yin (2009), a case study is an empirical inquiry that investigates a contemporary phenomenon within its real-life context. Madnick, Wang, Lee and Zhu (2009) supports the use of case study method, stating that it enable an in-depth inquiry of a single instance or event that can lead to deeper understanding of why and how that event happened. The ethnography research method is similar to the case study approach. It allows the researcher to participate overtly or covertly in people's daily lives for an extended time. Ethnography, according to Ritchie, Lewis, Nicholls and Ormston (2013), involves understanding of the social world of particular objects or subjects typically via immersion in their communities. In IS studies, the ethnographer join and become part of the IS environments and observe actors' behaviours and their interactions with the systems, which they are part of. A different perspective from the case study and ethnographic, is the action research. The action research requires experiments in which participants collaborate with the researcher to identify and solve problem of social practice, in real life situations. Järvinen (2007) upholds that action research includes the researcher as an active participant rather than a passive observer.

QUALITATIVE RESEARCH METHODS: DATA SOURCE

The data collection method involves the gathering of data relating to the subject (research) from sources, such as interview (Yin, 2009). According to Babbie and Mouton (2001), data source includes data collected by the researcher, such as transcripts

of the interviews and existing written documents. The data used in this study was gathered from a postgraduate student's field work. The candidate was registered with the department of Informatics, at the Namibia University of Science and Technology. The candidate selected the qualitative, case study approach, using the semi-structured interview technique for the data collection. Nineteen participants were interviewed in the process. This included senior and junior employees, from both technology and business units of the organisations that were used as cases in the study. The interviews were recorded, using a tape recorder, and later transcribed to a total of 39,000 words. The analysis of the data was guided by the Activity Theory. From the study, an enterprise architecture framework for the Namibian government-wide was developed. The data collection process was critical to the study.

QUALITATIVE RESEARCH METHODS: DATA COLLECTION PROCESS

Data collection is an important aspect of research, as it helps to determine the evaluation, success or

failure of IS studies. The data serve as the empirical evidence that is needed to resolve the problem at hand as expressed in a problem statement of the study. In qualitative, the main emphasis is on data collection which is in words rather than in numerical values. This priority of emphasis does not mean that information about frequency of events is irrelevant to qualitative enquiry (Erickson, 2012). Qualitative researchers also calculate totals and record frequencies of events when and where required, depending on the objectives of the study.

Qualitative data collection techniques that are used in IS studies include observations, interviews, documentation and open ended questionnaires. The techniques can be used complimentary with each other. The suitability of the techniques depends on the objectives of the study. The process becomes even more complex, but might be more holistic when more than one technique is selected and used. Figure1 below illustrates data collection process, which involves two techniques, semi-structured interviews and documentation, from qualitative perspective. The processes as explained below should be read with the diagram to gain better understanding of the process and its complexity.

Figure 1. Data collection process

Interview Questions

In interpretive studies, there are different types of interviews, which include structured, semi-structured and unstructured interviews. As shown in Figure 1, the focus is on the semi-structured interview technique. In achieving the research objectives, interview questions are extracted from the research questions. The interview questions form the written guidelines that are used to elicit information from the participants. The guidelines help the researcher to maintain consistencies, uniformity and orders during data collection, which contribute to improving the quality of the data.

The interview questions can also be generated from the documentations relating to the study. This occurs when the researcher finds items in documentations that can be linked to the research objectives. Hence it is necessary to request access to documentations that are related to the study before interview is embarked upon. However, data obtained from documentations could also sometimes require further clarification. In such an instance, the researcher incorporates them in the interview questions for clarity purposes. This process enhances data quality and richness.

Documentation

Documentation is a technique used to obtain or access documents that are related to phenomena being studied. The documents can be in hard or soft (electronic) copies. Documentation as a technique is used in data collection, to provide valuable data that could otherwise had been difficult or impossible to obtain if only the interviews technique was employed. The process was considered to be good, and did improve the quality of data. The process is often used for comparing and evaluating complementarity and alignment between participants' responses and what has been documented in the context of the study.

As revealed from experience-based, documents obtained for the purpose of a study should be reviewed as soon as it is practical, and not after the interview process is complete. This is primarily

because the documents can help the researcher to identify critical areas that might require further exploration and probing. Thus the researcher incorporates into the questions for the forthcoming interviews, therefore has the opportunity to probe and sought clarity.

Response

Response is the subjective opinion and perspective which interviewees associate and provide to the subject in question. In the process of the interview, the researcher should take written notes in order to capture as much as possible from the interviewees' responses. Thus, the researcher is strongly advised to listen attentively even if the interview is recorded. By so doing, the researcher stays focus and is able to grasp as much details, therefore, able to identify areas that need further probing and clarification.

Also, to be able to probe the responses further, the researcher must be knowledgeable about the area of study. Lack of knowledge of the subject obviously limits the researcher's ability to explore and probe the interviewees' responses. Hence it is critical to have done much work in the areas of literature review and studying related documentations before data collection is undertaken.

Probing is very crucial in interpretive studies, using the semi-structured interview technique in that it allows the researcher to expand on interview questions. This leads to collection of new information and enhances the data richness. There are likely gaps in the data as a result of lack of probing, which often emanate during analysis. There is no limit to the number of questions during probing of response. As shown in Figure 1, response can be iterative as probing continues. To end the probing process, the researcher repositions his or her questions.

Repositioning Questions

The purpose of repositioning is to avoid diverting away from the original topics during probing. It allows the interviewer to reconnect back with the

interview questions (guidelines). Reconnection with the interview questions enables the researcher to maintain the flow of the questions, towards achieving his or her objectives. Reposition become even more necessary when both interviewer and interviewee are passionate and very knowledgeable about the discourse, otherwise, the researcher lost track of the direction of the responses.

The implication of not connecting back to the interview questions as quickly as possible could be costly, in that the researcher might end up collecting quantitative data for qualitative purposes. This happens when “true or false” are offered as responses during probing. This is as a result of inconsistencies, which manifest from lack of flow in the questions being asked. Also, this could lead to respondents getting lost or confused in the process, as disjoint arise in the manner in which the interview questions are being posed. This makes it difficult to continue with the interview either from the interviewee’s or interviewers, or both perspectives. In addition, it becomes difficult or impossible for the researcher to link the sets of data during analysis.

Interview Continuation

Continuation is the step-by-step process of data collection, using the interview technique. It prevent disjoint, and strengthens focus during data collection, when using the interview technique within the qualitative paradigm. It happens, whether probing occurred or not in the process. However, if interviewee’s response requires further probing, continuation is done after the repositioning process is complete. If no probing is required, the researcher proceeds to the next question as outlined in the interview guideline.

Using the semi-structured technique, the interview process can be iterative. However, the process has to stop at some point. The process ceases when point of saturation is achieved. Saturation occurs when there are no more new and unique information is forthcoming, but rather repetition of what has been said or opined by other respondents.

To notice point of saturation, the researcher must be familiar with the data he or she has collected in the process. This can be achieved through transcribing of the recorded interviews immediately after each interview is conducted. As revealed from our experience, accumulating the interviews materials is a bad practise, and it limits the researcher’s chances of gathering rich data. This is primarily because the researcher will not be familiarised with the data that he or she has already collected, in order to identify where (if any) gaps exist.

Culmination

Culmination is referred to as, when data collection processes come to an end at some point during the study. This happens whether point of saturation is achieved or not. The end point could be initiated either by the researcher or the interviewee – when the researcher has exhausted the questions on the guideline, or the interviewee’s response leads to closure.

Culmination is considered to be the end of discussion between the researcher and the participants on matters relating to the phenomena being studied. Thereafter, the researcher performs data cleansing in preparation for analysis. This is done by correcting proof reading and editing, as well as appropriately labelling of the texts from the interviews. Without reaching the point of culmination, it is difficult to avoid disjoint and inconsistency in the data, which of course determines the findings.

MAJOR CHALLENGES IN AN INTERPRETIVE DATA COLLECTION PROCESS

The case study and semi-structured from the qualitative methods are considered to be more efficient for collection of rich data in IS studies. However, the data collection processes are not always as easy as we are meant to believe. Researchers often encounter challenges in collecting qualita-

tive data. This is caused by two main factors: (i) how well the researcher is knowledgeable about the technique he or she has employed for the data collection; and (ii) how familiar is the researcher with the environment within which data is being collected. However, the challenges vary from one researcher to the other. This section presents and discusses practical experience during a researcher's data collection in an interpretive study, using the semi-structured interview technique.

The most critical challenges that are often repeatedly encountered by researchers, particularly aspiring researchers and postgraduate candidates are discussed in this section. The challenges which include unconscious biasness, data size, knowledge of the subject and transcribing process determines and shapes the outcome of data that is collected in an interpretive study.

Expectation and Unconscious Biasness

In the qualitative paradigm, the interpretive approach attempt to understand a phenomenon that is being studied by exploring the meanings people assign to them, and within context (Lee, 1994). It does not predefine the phenomenon. However, researchers continue to misconstrue the guidelines of the interpretive approach as empirically gathered in the study that we did use as a case. The researcher explained:

When I went out to gather data I had expectations of the types of answers that I wanted to gather. I wanted to hear answers that sound good to my hearing, such that are well articulated and explained. These I had considered sensible according to my subjective reasoning at the time.

The interpretive research approach does not predefine dependent and independent variables, but focuses on human sense making within context (Myers, 1997). Even though it is difficult to completely separate the researcher from the phe-

nomenon, there shouldn't be specific expectation from the participants. However, some researchers do, as explained in this case:

I went to gather data with a mind-set of certain expectation from the respondents. So, as respondents shared and explained their views and perspectives which were completely different from what I had expected, I immediately concluded that they were not serious. Most of the times, I walked out of respondents' offices being angry, and felt that my time was wasted.

Following Klein and Myers (1999), it is against the principle of interpretive study to collect data with a pre-set mind. It poses a danger of reaching a conclusion before the evidences are gathered, and therefore defeating the purpose of the study. This triggers fundamental questions, such as, on what basis were judgements carried out on the respondents' views and opinions. According to the researcher in this case, most of the data that was thought to be useless became the corner stones, focal points during the analysis.

Data Size

The usefulness and relevance of qualitative data is not determined by the size or volume, but by its richness. According to the researcher, some interviews were too short, in that they lasted less than forty minutes. This was considered to be less useful at the time, even before the analysis was conducted. However, researcher does contribute to the size of the data that is collected as explained below:

In some interviews, when I did not get what I had expected, I immediately drew a conclusion that the respondent was not able to answer the question. As a result, he or she would not be able to answer the next question as well. I therefore lost interest and not continue. This contributed to making some of the interviews period to be short.

If the goal of the research problem is not to test the validity of a model where all the variables which influence a phenomenon or process is already known, then there is no need for expectation of answers from respondents. Also, the interpretive approach does not set out to test hypotheses; it is aimed at producing an understanding within context, whereby the phenomenon being studied influences and is influenced by the social context. Such culminative decision helps determine the data size, and could be attributed to the researcher's knowledge of the subject.

Knowledge of the Subject

Consultation on wide range of literature helps the researcher to gain deeper knowledge of the field of study. However, it has little or no influence on the data collection. According to Rowlands (2005), limitations in literature and the nature of the problem influence authors. Thus enabling the researcher to build on his or her knowledge, this is necessary in order to be able to engage in a robust conversation with the respondents during data collection. Otherwise, the researcher will be short of knowing what, when and how to probe the responses. This was evident in the study that was used in this case, as explained by the researcher:

Some of the interviewees were too short, due to the lack of probing of respondents' responses. The respondents would share their views, but in some cases I failed to follow up on them. I didn't think fast enough to see that an area needs further probing.

Some researchers learn as they progress in their studies. Others had vast knowledge about the phenomenon before they embarked on the data collection stage. On one hand, limited knowledge does not allow the researcher to take advantage of the flexibility which the interpretive approach presents, using semi-structured technique. On the other hand, vast knowledge could make the researcher lead the participants to specific direc-

tion or influence their views. The balance is a challenge, although it has been trivialised for long among researchers and postgraduate students.

Data Transcribing

The text and voice data are recorded with various types of infrastructures, such as cellular phones and tapes. Transcribing the recorded data can be rigorous, but critical to the richness. As such, it should be carried out with a high level of diligent and appropriateness. This includes the use of reliable infrastructures, for accurate audio. The researcher narrated her experience and challenges as follows:

The tape recorder was at some point not working properly, I only discovered that after the interview was completed. As a result, some of the valuable information was lost. It was difficult to reschedule an appointment due to the respondent's busy schedule. Also, the respondent had been disappointed if asked to repeat himself.

To organise and clean the data for analysis wholly depend on how well the researcher is familiar with the data. Also, data can get distorted during transcribing and documentation. Hence the role of the research in the management of the data is critical. One of the factors in the management of data is briefly explained as follows:

I did not complete transcribing some interviews while they were still fresh in my memory, and they piled up. When I had to transcribe them, I did not hear some of the words and sentences, and it became difficult to remember what respondent did say.

The outcome of one interview is a guide to conducting the next, in that it is used for corrective measure and improvement. It is therefore necessary for the researcher who transcribes the data to listen attentively to the audio. Also, to try to make sense of the data as the process continues.

This is to avoid discarding of valuable data. Thus the researcher explained, based on her experience:

When transcribing, listen attentively because the outcome of every interview is a guide to the next interview. As you transcribe the data, you identify gaps, due to lack of probing. So your next interview should be seen as an opportunity to fill the gaps.

Two critical factors, analysis and differentiation of data should be avoided during transcribing of the interviews' data. It is advisable to avoid analysis of the data until the transcribing is complete. This is mainly because sense making could be made out of "half of the data" only. Also, the researcher is not in a position to eliminate or consider data to be useful or useless until the transcribing is complete, and the data has been cleaned. Otherwise, the probability that the researcher would be biased is high. This implies that the authenticity of the outcome of the study could be affected.

FUTURE RESEARCH DIRECTIONS

For future research, the challenges revealed in this study can be explored to understand how they manifest themselves during data analysis and interpretation.

CONCLUSION

The qualitative methods enable the studies of new areas and theories on why and how the change takes place. Qualitative data helps researchers to interrogate and understand human behaviours as they interact with one another, as well as with objects in the development, implementation and use of IS/IT. Thus, it is critical to be unbiased in the collection of data. The quality and credibility of research data gives practitioners more confidence in considering the outcome in their practices and purposes.

Also, this chapter is intended to help researchers and postgraduate, to avoid pitfalls in their studies. It unveils some of the challenges which are commonly encountered by researchers and postgraduate in IS studies. Although some of the findings from the study might be common, they cannot be taken for granted. The article presents hands-on experience and uncovers critical pragmatic issues from the problem under study. The empirical and hands-on nature of the study is its main contribution, which makes it useful, especially for aspiring IS researchers.

KEY TERMS AND DEFINITIONS

Continuation: Sequential order in an interview process.

Culmination: A sudden dead-end.

Probing: Examination and further question based on response to previous question.

Repositioning: Readjustment to original structure of a guideline.

Saturation: A point where nothing new is forthcoming.

Cognitive and Psychological Factors in Cross-Language Information Retrieval

Rowena Li

Bayside High School Library, USA

INTRODUCTION

With the rapid growth of computer and communication technology, a global interconnected information infrastructure is quickly constructing through the Internet. As the information is able to travel beyond geographical and spatial borders via the Internet, and more and more people around the world have gained access to global networks, the language boundaries have to be crossed in order to make the global communication possible. Statistics shows that 74% of Internet users are non-English speakers (MiniWats Marketing Group, 2015). However, English is still the leading language in global communication environment. English language dominates 54.4% of the websites (W3Techs.com, 2015). As the Internet has become one of the major communication mechanisms for information storage, retrieval, and dissemination, users need the ability to locate and retrieve information wherever, whenever and in whatever the language it has been stored. However, most of the search engines currently available can only provide monolingual information retrieval, which means that the retrieval can only be conducted in the same language as the query language. Cross-language information retrieval (CLIR) has become increasingly important to facilitate the effectiveness of information exchange among different languages. As a result, the study and development of tools and technology of cross-language information retrieval have gained greater attention over the past decade. While a lot of research has focused on the effectiveness of system functionality, few studies have examined information needs and so-

cial aspects related to cross-language information retrieval. This article aims to speculate the human and social aspects of cross-language information retrieval. It explores CLIR users' unique social and cultural contexts, their psychological and cognitive structures, and their distinctive relevance judgment. It examines in depth the barriers embedded in cultural, linguistic, and cognitive dimensions, which might hinder further advancement in cross-language information retrieval.

BACKGROUND

Information Seeking

Information has been traditionally viewed as a message transmitted from sender to receiver through a channel which may reduce or increase its ambiguity (Shannon & Weaver, 1949). In this view, information is external and objective, as well as structured and measurable. Dervin (1976, 1980, & 1983) rejected this traditional approach and proposed her sense-making theory, which concerns the behavioral, cognitive and social aspects of information seeking. She introduced information seeking as a concept that an individual has to constantly "make sense" of his situation to move physically and cognitively across a gap in front of him through time and space. This model sees information seeking as systematic, subjective, situational, individual, cognitive, and holistic (Dervin & Nilan, 1986). In her own way, Dervin recognizes the similarity in information seeking process, as well as understands the uniqueness

of individuals in information seeking situation. Saracevic, Kantor, Chamis, and Trivison (1988) associated information seeking process with users' *perception of the problem, intent for use of the information, internal knowledge state, and public knowledge expectations*. Wilson's model (1981) states that an individual's situation and social role, his/her psychological and cognitive states influence his/her context of information need. Other cognitive approaches to information seeking were also presented in the past two decades. Bates' "berry-picking" model (1989) states that information seeking is not linear, but is constantly modified by the feedback occurred in information seeking process. Belkin's ASK (Anomalous State of Knowledge) model states that information seeking arises when an individual cannot identify the gap in his knowledge state (Belkin, Oddy, & Brooks, 1982). Taylor's (1991) situational theory believes that information seeking is not only "based on subject matter, but on other elements of the context within which a user lives and works" (p. 218). Kuhlthau's (1991) Information Search Process approach believes that individuals seek meaning rather than answers. Affective states are influenced by uniqueness of information situation and mood states. And personal involvement influences the information seeking process. Ingwersen's (1992, 1996) cognitive model states that cognition occurs in all stages of information seeking, and individuals experience a variety of cognitive modeling. Furthermore, Ellis's information seeking theory (1989), Schamber's relevance (Schamber, Eisenberg, & Nilan, 1990), and Wilson's situational relevance (1973) have also influenced information seeking research.

In general, for the past two decades, the study of information has experienced a paradigm shift. It concentrates more on subjectivity (instead of objectivity) of information, on holistic (instead of atomistic) view of experience, and on internal cognition (instead of external behavior). And at the same time, users have become a part of information process and a significant factor in the study of information seeking and retrieval.

Information Retrieval and Cross-Language Information Retrieval

Information retrieval (IR) is "a field concerned with the structure, analysis, organization, storage, searching, and retrieval of information" (Salton, 1968, p. v). It is the process of query formulation, matching, selection, evaluation and representation. The result is presented in the form of a ranked list in a descending order according to their relevance to the query. Information retrieval process is evaluated by the effectiveness and relevance of this returned list to the search query.

Cross-language information retrieval (CLIR) is a special case of information retrieval. It focuses on retrieving documents in languages other than query language. This process involves not only information retrieval, but also query translation to locate relevant documents. CLIR is defined as "Given a query in any medium and any language, select relevant items from a multilingual multimedia collection which can be in any medium and any language, and present them in the style or order most likely useful to the user, with identical or near-identical objects in different media or languages appropriately identified" (Fluhr et al., 1999).

CLIR Models and Approaches

The process of CLIR involves query formation, document pre-processing, index matching, document selection, document examination, document delivery, and relevance feedback (Oard & Diekema, 1998).

Of all the stages of information retrieval process, matching is the most important and problematic one. To better match a query to the indexed terms of pre-processed documents, four matching strategies have been identified. They are *cognate matching*, *query translation*, *document translation*, and *interlingual techniques* (Oard & Diekema, 1998).

Oard and Diekema (1998) indicated that *cognate matching* is the process of matching words

from one language to another according to the words' spelling or pronunciation. This approach is used to find matches when the query words are not in the dictionary, but only under a condition - the two languages are in the same language group. *Query translation* is the most used strategy. The query is translated into target languages. Afterwards, the translation is used to match the documents for relevant retrieval. The advantage of query translation is its efficiency. However, since the query contains only a few words, the translation might lead to lexical ambiguity due to lack of context. *Document translation* is to automatically translate documents into query language. It involves online real-time machine translation system for users to navigate the Internet. However, it requires large system functionality. Since it is costly and time-consuming, it is only limited to smaller collections. *Interlingual techniques* convert both query and index terms from the documents into a unified language-independent representation. Multilingual thesauri are used in this concept. Since the controlled-vocabulary representation generates only one term for each concept, query and document representations can map their words respectively onto their unique terms in the thesauri. This approach reduces translation ambiguity. However, it requires additional storage space for the translated documents.

CLIR Users and Their Information Needs

Users have various information needs. As users possess different language skills and information seeking tasks, their information needs and information seeking behavior are different. CLIR users basically fall in two categories:

1. Monolinguals search documents/images in target language(s) that they do not know by entering a query in a language they know;
2. Multilinguals search documents/images in target language(s) they know by entering a query in one language.

Large organizations may also be users of CLIR. Commercial online services such as Dialog and LexisNexis have developed retrospective market searches and alert services (Oard, 1997). CLIR may help expand the market for these services. Individual government and international institutions also have the demand to search a large amount of multilingual documents. Journalists may look for news and stories in foreign language newspapers, and business analysts might gather foreign business information and provide service to different countries. Translators may use CLIR services to serve clients in other countries, and information specialists may search as intermediaries for patrons (Petrelli, Beaulieu, Sanderson, & Hansen, 2002). Furthermore, scholars may search documents for current development in their research fields.

CLIR Information Seeking Behavior

There has been a paradigm shift from a system-centered approach toward a user-centered approach in the study of human information seeking behavior since the 1980s. Onscreen reading time and printing behavior have been used as a useful source of implicit feedback to indicate the relevance of the retrieval output (Kim, Oard, & Romanik, 2000). Personality and situation (Petrelli et al., 2002), cognition state (Foster, 2004), the language used (Al-Wreikat, Rafferty, & Foster, 2015) also influence users' information seeking behavior. In addition, knowledge of target language affects users' general information seeking behavior. Users make faster relevant judgments based on the retrieval output if they know target language well (Józsa, Köles, Komlódi, Hercegfli, & Chu, 2012).

HUMAN AND SOCIAL ASPECTS OF INFORMATION SEEKING

Social and Cultural Contexts in CLIR

In the process of CLIR, machine translation is used to translate either the query or the full text

documents. However, translation errors impact CLIR performance and these errors occur because of two issues: the lack of equivalent lexical terms in target language, and conceptual domains of the query are different from those of the retrieved documents in target language.

The process of translation involves not only the technical and structural transferring information, but also cultural transferring from one language to another (Gransow, 2001). Some shared perceptions and concepts are universal between languages. Some concepts exist only in a specific context because of cultural differences. As a result, the receiver might not be able to perceive the world presented by the sender through mere linguistic translation. Especially with non-translatable indigenous concepts, the words-to-words translation is simply not enough (Riggs, 1987).

Language reflects culture. Through translation, the culture of source language should be reflected in target language via a linguistic filter. Therefore, translation is not merely a word-for-word process; rather, it filters through linguistic, stylistic and cultural phenomenon transparently. Translation is also tied to other aspects of hu-

man knowledge, such as psychology, sociology, anthropology, history, linguistics and geography (Castro-Paniagua, 2000). An exclusion of all these factors in translation will result in transferring only a partial picture of the given messages across languages. When the cultures between the two languages are totally different, the culture embedded in source language should be transferred and explained into target language and be adopted into target language. Otherwise, the translation only delivers the linguistic meaning of the words, not the culture embedded.

Essentially, a word has two representative levels, a lexical level and a conceptual level. When a word is emic, which exists within a culture and determined by local custom and belief, it is hard to map this word at both its lexical and conceptual levels. This creates a lexical hole in machine translation. Even when a word is etic, which is not culturally specific and can be applied to any cultural practices, the conceptual level of a word might not be easily mapped to that of a corresponding word in another language, because some cultural elements may not be the same. Figure 1 demonstrates a translation process.

Figure 1. Mapping model for translating a word from one language to another

This model shows even though a source word can be mapped to its target language on a lexical level, some of the cultural elements might be lost in translation process, because those cultural elements at the conceptual level are local and specific to that culture. As a result, users might be confused with the mismatch between the language and the context. For example, 江南一叶 is a well-known Chinese phrase, which cannot be found in any dictionaries. Figure 2 indicates two translation processes taken from lexical and conceptual levels with and without the knowledge of Chinese culture. The images from the two translations are totally different due to implementing or missing cultural elements on the conceptual level.

Unfortunately, in the study of CLIR, great efforts have been made to solve the problems of words mismatch and ambiguity. Little research has focus on the consideration of mapping cultural-situational concepts from source language to target language in translation process.

Psychological and Cognitive Structure in CLIR

It is clear that translation errors are not just the result of linguistic or lexical mismatches, they also relate to translator's cognitive state, which links the linguistic choices to culturally determined conceptual preferences. Generally, four cognitive variables affect users and context of information seeking: *problem*, *internal knowledge state*, *intent*, and *public knowledge estimate* (Saracevic et al., 1988). The initial information seeking process starts with the emergence of a cognitive dissonance when the user realizes there is a gap between his internal knowledge state and reality (Saracevic et al., 1988; Wilson, 1997). With the intention of filling this gap, he makes his public knowledge estimate prior to information seeking process. During his information seeking, users bring two types of "knowledge structures" - episodic memory (personal information) and semantic memory

Figure 2. Translation process models with/without the knowledge of culture

Figure 4. Cognitive state of a multilingual in a CLIR process

language in their mind and compare them to the original search terms.

Figure 4 shows that each language is stored separately at the lexical level. However, at the conceptual level, words in each language access a shared semantic representation. The features in conceptual memory activated by the word in source language in lexical memory may not necessarily be activated by its target language translation (de Groot, 2002; Luna & Peracchio, 2002). As a result, although the word is translated lexically, the meanings of the two words might be different semantically, because the contexts in which the words are being used are different between cultures and languages. This indicates that culture and cognitive states of the information seeker influence the process of information seeking.

Subjective Relevance in CLIR

Relevance has been a major criterion for evaluating the effectiveness of information retrieval. It is a measure in degrees of how close the relationship is between a query and the contents of the retrieved documents. Traditionally, relevance has

been judged through laboratory models, which consist of three parts: a document database, a set of topical requests, and a machine-run binary assessment algorithm. This model has been challenged recently by an emphasis on user-centered information design and human interaction in information retrieval. As a result, researchers start to focus their studies on subjective relevance in addition to objective relevance (Ingwersen & Järvelin, 2005). Subjective relevance refers to the usefulness of documents in relation to the goals in a situation perceived by the user himself subjectively (Borlund & Ingwersen, 1998). This has changed the course of relevance study - relevance is measured not only by the algorithm produced from binary computer programs, users' personal information needs, language skills, knowledge, perceptions, interaction, and intentions influence relevance measure as well. In a sense, relevance expanded to include its subjective (instead of objective), dynamic (instead of static) and situational (instead of algorithmic) dimensions (Schamber, 1994). The once fixed measure of system-based relevance becomes dynamic when applied to diverse users and various situations.

Since CLIR is a special case of information retrieval, user's language skills and cognitive structures should be considered in its relevance measure. In the process of CLIR, a multilingual types a query in source language and expects to retrieve relevant documents in target language. As he sends in the query, he has some index words envisioned in his mind in target language. This envisioned index words are conditioned by his language skills and his cultural knowledge in the conceptual level. When the documents are retrieved in target language, he compares and evaluates the relevance of the retrieved documents based on his expected index words pre-formed in his mind, and this process also depends on his language skills and his cultural backgrounds. Figure 5 demonstrates subjective relevance process in CLIR.

Users are the final judges of relevance measure, since information retrieval systems are built for users instead of lab-run system assessment. Users'

language skills and their knowledge of culture have a great impact on their information seeking experience and information seeking behavior. It also influences their relevance judgments.

1. The more the user knows the subject matter, the easier the judgment is made on the relevance;
2. The more the user knows target language and its cultural contexts related to the subject matter, the fewer documents of a retrieval set he tends to judge relevant;
3. The more the user knows target language and its cultural context related to the subject matter, the less time he spends on the retrieval process;
4. The more the user knows target language and its cultural context related to the subject matter, the more frequent he revises the query and starts new rounds of information retrieval.

Figure 5. Cross-language information retrieval model with the influence of the knowledge of culture on subjective relevance

FUTURE RESEARCH DIRECTIONS

After more than a decade of research on cross-language information retrieval, information retrieval systems have been greatly improved to accurately translate queries and to effectively retrieve relevant information in target language. However, recall and precision still remain as the top two challenges. When we look into the problems of ambiguity and mismatch, the dimensions of cultural context, psychological and cognitive structure, and situational relevance are not to be overlooked. Further study of these three dimensions will open another window in designing a user-centered system and in reinforcing the concept of user-system interactions.

The four models presented in this article are not generated from surveys, observances, or laboratory research. They have not been substantiated through data collection and analysis. Further studies need to concentrate on verifying these models statistically. Further investigations may also focus on defining the associations of multilinguals' fluency level in target language and their relevance judgment. Observations and lab samplings might be used to collect data and to establish a foundation for further study.

CONCLUSION

Cross-language information retrieval system users are unique in their information seeking process. Their psychological and cognitive states are different from those of monolingual information system users. Their language skills, social and cultural backgrounds, situational and personal perceptions become important variables in measuring relevance in information retrieval. To establish a user-centered interactive cross-language information retrieval system, an early feedback system should be considered. As indicated, monolinguals compare their query to the returned index terms in source language and make relevance judgment (Figure 3), and multilinguals compare their expected index terms in target language to the

returned index terms (Figure 4), an interactive system should be set up to present multiple query translations right after the query is entered. As a result, before machine matches query to index terms in database documents, users are able to choose the best lexical translation equivalents that are culturally appropriate in particular situational contexts. In this way, the number of retrieved irrelevant documents shall be reduced and its recall and precision will be improved.

In general, it is imperative to focus on the human and social aspects in the examination of cross-language information retrieval process. The influence of culture and users' target language skills on the process of CLIR should be further investigated. Although much attention has been concentrated on solving the problems of words mismatch and ambiguity in the course of translation, users' cognitive and psychological development and progress involved in CLIR process should never be overlooked.

KEY TERMS AND DEFINITIONS

Cross-Language Information Retrieval:

The process of locating relevant documents from a large collection of data in a language which is different from the query language.

Information Retrieval: The process of locating relevant documents from a large collection of data in physical and electronic forms.

Objective Relevance: The degree of precision and recall of the retrieved information to the query measured objectively by machine-run binary assessment algorithms.

Source Language: The language used in a query.

Subjective Relevance: The degree of precision and recall of the retrieved information to the query perceived subjectively by the user.

Target Language: The language used for the retrieved information, usually different from source language.

A Fast and Space-Economical Algorithm for the Tree Inclusion Problem

Yangjun Chen

University of Winnipeg, Canada

Yibin Chen

University of Winnipeg, Canada

INTRODUCTION

Let T be a rooted tree. We say that T is *ordered* and *labeled* if each node is assigned a symbol from an alphabet Σ and a left-to-right order among siblings in T is specified. Let v be a node different of the root in T with parent node u . Denote by $delete(T, v)$ the tree obtained by removing the node v from T , by which the children of v become part of the children of u as illustrated in Figure 1.

Given two ordered labeled trees P and T , called the pattern and the target, respectively. We may ask: Can we obtain pattern P by deleting some nodes from target T ? That is, is there a sequence $v_1, \dots, v_k$ of nodes such that for

$$T_0 = T \text{ and}$$

$$T_{i+1} = delete(T_i, v_{i+1}) \text{ for } i = 0, \dots, k-1,$$

we have $T_k = P$? If this is the case, we say, P is included in T (Kilpeläinen and Mannila, 1995).

Such a problem is called the *tree inclusion problem*. It has many applications in the computer engineering as described below.

BACKGROUND

The first interesting application of the tree inclusion is used as an important query primitive for XML data (Mannila and R  iha, 1990), where a structured document database is considered as a collection of parse trees that represent the structure of the stored texts and the tree inclusion is used as a means of retrieving information from them. As an example, consider the tree shown in Figure 2, representing an XML document for the book *Arts of Programming* authored by (Knuth, 1969). One might want to find this book in an XML database by forming a pattern tree as shown in Figure 3 as a query, which can be obtained by deleting some nodes from the tree shown in Figure 2. Thus, a tree inclusion checking needs to be conducted to evaluate this query.

Figure 1. Illustration of node deletion

DOI: 10.4018/978-1-5225-2255-3.ch391

Figure 2. A XML document (target) tree

Figure 3. A pattern tree

Another application of this problem is to query the grammatical structures of *English* sentences, which can also be represented as an ordered tree since a sentence can always be divided into several ordered components such as noun phrases, verb phrases, and adverbs; and a noun phrase itself normally contains an article and a noun while a verb phrase may contain a verb, a noun phrase, an adverb, and so on. To check whether a concrete sentence is grammatically correct, we will represent it as a pattern tree and make a tree inclusion checking against some target grammatical tree structures.

A third application of the ordered tree inclusion is the video content-based retrieval. According to (Rui and Huang, 1999), a video can be successfully

decomposed into a hierarchical tree structure, in which each node represents a scene, a group, a shot, a frame, a feature, and so on. Especially, such a tree is an ordered one since the temporal order is very important for video. Some other areas, in which the ordered tree inclusion finds its applications, are the scene analysis, the computational biology, such as *RNA* structure matching (Lyngs, Zuker and Pedersen, 1999), and the data mining, such as tree mining discussed in (Zaki, 2002), just to name a few.

Up to now, the best algorithm for this problem requires $O(|T| + |P|)$ space and $\Theta(|T| \cdot |\text{leaves}(P)|)$ time (Alonso and Schott, 1993; Chen, 1998; Chen and Chen, 2006; Bille and Gørtz, 2011), where $\text{leaves}(P)$ stands for the set of the leaves of P .

In this chapter, we propose an efficient algorithm for this problem. Its time and space complexities are bounded by $O(|T| \cdot \min\{h_p, |\text{leaves}(P)|\})$, and $O(|T| + |P|)$, respectively, where h_p is the height of P , defined to be the number of edges on the longest downward path from the root to a leaf node.

BASIC DEFINITIONS

In this section, we mainly define the notations that will be used throughout the paper. Let T be a

labeled tree that is ordered, i.e., the order between siblings is significant. We denote the set of nodes and edges by $V(T)$ and $E(T)$, respectively. The size of T is denoted by $|T|$.

Technically, it is convenient to consider a slight generalization of trees, namely forests, which are defined to be a set of disjoint trees. A tree T consisting of a specially designated node $root(T) = t$ (called the root of the tree) and a forest $\langle T_1, \dots, T_k \rangle$ (where $k \geq 0$) is denoted as $\langle t; T_1, \dots, T_k \rangle$. We also call T_j ($1 \leq j \leq k$) a direct subtree of t .

Let u, v be two nodes in T . If there is path from node u to node v , we say, u is an ancestor of v and v is a descendant of u . In this paper, by *ancestor* (*descendant*), we mean a proper ancestor (descendant), i.e., $u \neq v$. We will use $u \Rightarrow v$ to represent that u is a proper ancestor of v .

The ancestorship in a tree can be checked very efficiently by using a kind of tree encoding (Chen, 2006), which labels each node v in a tree with an interval $I_v = [a_v, b_v]$, where b_v denotes the rank of v in a *post-order* traversal of the tree. Here the ranks are assumed to begin with 1, and all the children of a node are assumed to be ordered and fixed during the traversal. Furthermore, a_v denotes

the lowest rank for any node u in $T[v]$ (the subtree rooted at v , including v). Thus, for any node u in $T[v]$, we have $I_u \subseteq I_v$ since the post-order traversal visits a node after all its children have been visited. In Figure 4, we illustrate such a tree encoding, assuming that the children are ordered from left to right. It is easy to see that by interval containment we can check whether two nodes are on a same path. For example, $v_3 \Rightarrow v_{10}$, since $I_{v_3} = [1, 5]$, $I_{v_{10}} = [3, 3]$, and $[3, 3] \subset [1, 5]$; but v_9 is not reachable from v_2 since $I_{v_2} = [10, 13]$, $I_{v_9} = [1, 2]$, and $[1, 2] \not\subset [10, 13]$.

Let $I = [a, b]$ be an interval. We will refer to a and b as $I[1]$ and $I[2]$, respectively.

Lemma 1: For any two intervals I and I' generated for two nodes in a tree T , one of four relations holds: $I \subset I'$, $I' \subset I$, $I[2] < I'[1]$, or $I'[2] < I[1]$.

Based on Lemma 1, the left-to-right ordering of nodes can also formally be defined. A node u is said to be to the left of v if they are not related by the ancestor-descendant relationship and v fol-

Figure 4. Illustration for tree encoding

lows u when we traverse T in preorder. Then, u is to the left of v if and only if $I_u[2] < I_v[1]$.

In the following, we use $<$ to represent the left-to-right ordering. Also, $v \leq v'$ iff $v < v'$ or $v = v'$. The following definition is due to [9].

Definition 1: Let F and G be labeled ordered forests. We define an ordered embedding (φ, G, F) as an injective function $\varphi: V(G) \rightarrow V(F)$ such that for all nodes $v, u \in V(G)$,

1. $\text{label}(v) = \text{label}(\varphi(v))$; (label preservation condition)
2. $v \Rightarrow u$ iff $\varphi(v) \Rightarrow \varphi(u)$, i.e., $I_u \subset I_v$ iff $I_{\varphi(u)} \subset I_{\varphi(v)}$; (ancestor condition)
3. $v < u$ iff $\varphi(v) < \varphi(u)$, i.e., $I_v[2] < I_u[1]$ iff $I_{\varphi(v)}[2] < I_{\varphi(u)}[1]$. (sibling condition) $\square$

If there exists such an injective function from $V(G)$ to $V(F)$, we say, F includes G , F contains G , F covers G , or say, G can be embedded in F . Figure 5 shows an example of an ordered tree inclusion.

Let P and T be two labeled ordered trees. An embedding φ of P in T is said to be *root-preserving* if $\varphi(\text{root}(P)) = \text{root}(T)$. If there is a root-preserving embedding of P in T , we say that the root of T is an occurrence of P . Figure 5b also shows an example of a root preserving embedding. According to (Kilpeläinen and Mannila,

1995), restricting to root-preserving embedding does not lose generality. In fact, the method to be discussed works top-down and always tries to find root-preserving subtree embeddings. Throughout the rest of the paper, the outdegree of v in a tree is denoted by $d(v)$ while the height of v is denoted by $h(v)$. The height of a leaf node is set to be 0. In addition, we refer to the labeled ordered trees simply as trees.

Throughout the rest of the paper, the outdegree of v in a tree is denoted by $d(v)$ while the height of v is denoted by $h(v)$. The height of a leaf node is set to be 0. In addition, we refer to the labeled ordered trees simply as trees.

MAIN IDEA: CUTS

The main idea of our algorithm consists in a mechanism called *cut checking* introduced into a top-down tree search to get rid of useless computation.

Let $T = \langle t; T_1, \dots, T_k \rangle$ ($k \geq 0$) be a tree and $G = \langle P_1, \dots, P_q \rangle$ ($q \geq 0$) be a forest. We handle G as a tree $P = \langle \nu_G; P_1, \dots, P_q \rangle$, where ν_G represents a virtual node, matching any node in T . Note that even though G contains only one single tree it is considered to be a forest. So a virtual root is added. Therefore, each node in G , except the virtual node, has a parent.

Figure 5. (a) The tree on the left can be included in the tree on the right by deleting the nodes labeled: f and e ; (b) the embedding corresponding to (a)

Consider a node v in $G = \langle P_1, \dots, P_q \rangle$ with children $v_1, \dots, v_k$. We use a pair $\langle [i, j], v \rangle$, called an *interval* rooted at v , to represent an ordered forest $\langle G[v_i], \dots, G[v_j] \rangle$ made up of a series of subtrees rooted at $v_i, \dots, v_j$, respectively. Especially, $\langle [1, i], v \rangle$ (or simply denoted as $\langle i, v \rangle$) represents an ordered forest containing the first i subtrees of v : $\langle G[v_1], \dots, G[v_i] \rangle$. If v is ν_G , or a node on the left-most path in P_1 , $\langle i, v \rangle$ is called a *left-corner* of G [5]. Obviously, $\langle i, \nu_G \rangle$ is a left-corner, representing the first i subtrees in G : $P_1, \dots, P_i$. So, $\langle q, \nu_G \rangle$ stands for the whole G .

In addition, we will use $\langle i, v \rangle$ to represent the forest $\langle G[v_{i+1}], \dots, G[v_k] \rangle$, referred to as the complement of $\langle i, v \rangle$. When it is clear from a context, we may use $\langle G[v_i], \dots, G[v_j] \rangle$ and $\langle [i, j], v \rangle$ interchangeably without causing any confusion.

Let u be a node on the left-most path in P_1 . Let $\langle i, v \rangle$ be a left-corner of $G = \langle P_1, \dots, P_q \rangle$. If $v = u$, we say that $\langle i, v \rangle$ and u are *level-equal*, denoted as $\langle i, v \rangle \cong u$. If v is an ancestor of u , we say, $\langle i, v \rangle$ is higher than u , denoted as $\langle i, v \rangle \succ u$. Then, $\langle i, v \rangle \preceq u$ represents that $\langle i, v \rangle$ is higher than or level-equal to u .

In particular, we will use $A(T, G) = \langle i, v \rangle$ to represent a checking of G against T , returning a left-corner $\langle i, v \rangle$ in G with the following properties:

- If $i > 0$ and v is not the left-most leaf node, it shows that
 - The first i subtrees of v can be embedded in T ;

- For any $i' > i$, $\langle i', v \rangle$ cannot be embedded in T ; and
- For any v 's ancestor u on the left-most path in G , there exists no $j > 0$ such that $\langle j, u \rangle$ is able to be embedded in T .
- If $i = 0$ or v is the left-most leaf node of G (denoted as $\rho(G)$), it indicates that no left-corner of G can be embedded in T .

In this sense, we say, $\langle i, v \rangle$ is the *highest* and *widest* left-corner which can be embedded in T .

Now we consider a tree T and a forest G shown in Figure 6, in which each node in T is identified with t_i , such as t_1, t_2, t_{11} , and so on; and each node in G is identified with p_j . Besides, each subtree rooted at t_i (p_j) is represented by T_i (resp. P_j).

In order to check whether T includes $G = \langle P_1, P_2 \rangle$, we can first check whether T_1 alone includes G . That is, we will perform a recursive call as follows:

$$A(T, \langle P_1, P_2 \rangle) \rightarrow A(T_1, \langle P_1, P_2 \rangle).$$

Assume that $A(T_1, \langle P_1, P_2 \rangle)$ returns $\langle i, v \rangle$. We may have one of three cases:

Case 1: $\langle i, v \rangle = \langle 2, \nu_G \rangle$.

Case2: $\langle i, v \rangle = \langle 1, \nu_G \rangle$.

Case 3: $v \neq \nu_G$, but a node on the left-most path in P_1 . That is, T_1 contains only a left-corner not higher than p_1 .

Figure 6. A tree and a forest

Figure 7. A target and a pattern tree

In Case 1, T_1 contains G .

In Case 2, T_1 contains only P_1 , and we will call $A(T_2, \langle P_2 \rangle)$ in a next step.

In Case 3, we will continually check whether T_2 alone is able to include G (by calling $A(T_2, \langle P_1, P_2 \rangle)$). This time, however, we will use v (in $\langle i, v \rangle$) to control the working process to cut off part of the computation once we find that a left-corner higher than v cannot be produced. It is because such a computation will not make any contribution to the final result due to the following observation.

Assume that $A(T_2, \langle P_1, P_2 \rangle)$ returns $\langle i', v' \rangle$ with $v = v'$ or $v \Rightarrow v'$. Then, in a next step, we will check T_3 against $\langle P_1, P_2 \rangle$ by calling $A(T_3, \langle P_1, P_2 \rangle)$. If its return left-corner is higher than v , then we will use this left-corner as the return value of $A(T, \langle P_1, P_2 \rangle)$. Then, $\langle i', v' \rangle$ is not used. If its return left-corner is not higher than v , we will make a *supplement checking* of $\langle T_2, T_3 \rangle$ against $\langle i, v \rangle$ to see whether $\langle T_2, T_3 \rangle$ is able to embed some subtrees in $\langle i, v \rangle$. Assume that $\langle T_2, T_3 \rangle$ embeds the first j subtrees in $\langle i, v \rangle$. Then, the return value of $A(T, \langle P_1, P_2 \rangle)$ should be $\langle i + j, v \rangle$. In this case, $\langle i', v' \rangle$ is not used, either, in terms of the following analysis:

If $v \Rightarrow v'$, or $v = v'$ but $i' \leq i$, $\langle i', v' \rangle$ is obviously useless for the final result. However, even

if $v = v'$ with $i' > i$, it is still useless since in this case, there is definitely an integer $j \geq i' - i$ such that $\langle T_2, T_3 \rangle$ embeds the first j subtrees in $\langle i, v \rangle$, and the supplement computation will find this embedding.

The above discussion shows that if $A(T_2, \langle P_1, P_2 \rangle)$ cannot return a left-corner higher than v , the corresponding work is futile and should be avoided. However, avoiding the whole work seems not possible. Yet we can really effectively block a significant part of the useless computation by using the partial results obtained in the previous steps, as illustrated in Example 1.

Example 1: Consider the tree T and the forests G shown in Figure 7.

In order to check whether T includes G , we will first check T_1 against $G = \langle P_1, P_2 \rangle$. Obviously, T_1 is not able to embed G . However, it can embed P_{11} and therefore the return value of this checking should be $\langle 1, p_1 \rangle$. In a next step, we will check T_2 against G , and try to see if T_2 alone is able to embed G . But this time, p_1 will be utilized to control the process. More specifically, it will effectively block the checking of T_2 against P_{11} since this checking can only possibly return a left-corner not higher than p_1 . $\square$

We refer to a node like p_1 in Example 1 as a *cut*.

ALGORITHM

In this section, we present our basic algorithm $A(T, G)$ to check a tree $T (= \langle t; T_1, \dots, T_k \rangle)$ against a forest $G (= \langle P_1, \dots, P_q \rangle)$. The algorithm works in a multiple recursive way in the sense that different kinds of recursive calls will be carried out in terms of different characteristics of inputs. As a whole, two general cases need to be recognized:

In Case 1, we have $G = \langle P_1 \rangle$; or $G = \langle P_1, \dots, P_q \rangle$ with $q > 1$, but $|T| \leq |P_1| + |P_2|$. In this case, what we can do is to check T against P_1 since it is not possible for T to embed more than one subtree in G .

In Case 2, we have $G = \langle P_1, \dots, P_q \rangle$ with $q > 1$, and $|T| > |P_1| + |P_2|$. In this case, we will check $\langle T_1, \dots, T_k \rangle$ against the whole G since in this case we may have a sequence of subtrees $T_1, \dots, T_{l_m}$ with each being able to embed some subtrees in G . For this reason, we define two subfunctions: α -function and β -function, used to handle Case 1 and Case 2, respectively:

$$\alpha(T, P_1) = \langle i, v \rangle, \quad (1)$$

where $\langle i, v \rangle$ is a highest and widest left-corner in P_1 , which can be embedded in T .

$$\beta(\langle T_1, \dots, T_k \rangle, G) = \langle j, u \rangle, \quad (2)$$

where $\langle j, u \rangle$ is a highest and widest left-corner in G , which can be embedded in $\langle T_1, \dots, T_k \rangle$.

Here, our intention is quite straightforward:

In Case 1 we will call $\alpha(T, P_1)$ and in Case 2 we will call $\beta(\langle T_1, \dots, T_k \rangle, G)$. However, during the working process, they may call each other recursively.

Additionally, in Case 2, the return value $\langle j, u \rangle$ of $\beta(\langle T_1, \dots, T_k \rangle, G)$ needs to be further checked as follows:

- If $u \neq p_1$'s parent, check whether $\text{label}(t) = \text{label}(u)$ and $j = d(u)$. If it is not the case, the return value of $A(T, G)$ is the same as $\langle j, u \rangle$. Otherwise, the return value of $A(T, G)$ should be set to $\langle 1, u$'s parent $\rangle$, showing that T includes $G[u]$. (For this reason, $d(v_G)$ is set to be ∞ , larger than the outdegree of any node in both T and G .)
- If $u = p_1$'s parent, the return value of $A(T, G)$ is the same as $\langle j, u \rangle$, showing that T embeds $\langle P_1, \dots, P_j \rangle$.

By using the α -function and the β -function, the algorithm can be described as shown in Function 4, in which node v (as the third input) works as a cut.

*Function 4. $A(T, G, v)$ (*Initially, cut v is set to be $\rho(G)$.*)*

Input: $T = \langle t; T_1, \dots, T_k \rangle, G = \langle P_1, \dots, P_q \rangle$.

Output: a left corner.

Begin

```

1.   if  $p_1$ 's parent is not an ancestor of  $v$  then return  $\langle 0, \rho(G) \rangle$ ;
2.   if  $(q = 1 \text{ or } |T[t]| \leq |G[p_1]| + |G[p_2]|)$  (*Case 1*)
3.   then return  $\alpha(T, P_1, v)$ 
4.   else if  $\text{label}(t) = \text{label}(v)$  (*Case 2*)
5.       then  $\langle j, u \rangle := \beta(\langle T_1, \dots, T_k \rangle, G, v$ 's first child);
6.       else  $\langle j, u \rangle := \beta(\langle T_1, \dots, T_k \rangle, G, v)$ ;
7.       if  $v \neq p_1$ 's parent
8.       then if  $(\text{label}(t) = \text{label}(u) \wedge j = d(u))$ 
9.           then return  $\langle 1, u$ 's parent  $\rangle$ ;
10.      return  $\langle j, u \rangle$ ;
end
```

Figure 8. A pattern tree

In the following, both the α -function and β -function will be discussed in great detail.

• α -function

In order to implement the α -function, we need to associate each node v in G with a link to the left-most leaf node in $G[v]$, denoted as $\delta(v)$, as illustrated in Figure 8.

Let v' be a leaf node in G . $\delta(v')$ is defined to be a link to v' itself. So in Figure 8, we have $\delta(v_1) = v_1$, $\delta(v_2) = v_2$, $\delta(v_3) = v_3$, $\delta(v_4) = v_4$, $\delta(v_5) = v_5$, $\delta(v_6) = v_6$, $\delta(v_7) = v_7$, and $\delta(v_8) = v_8$. Denote by $\delta^{-1}(v')$ a set of nodes x such that for each $v \in x$ $\delta(v) = v'$. Thus, in Figure 8, we have $\delta^{-1}(v_4) = \{v_1, v_2, v_3, v_4\}$, $\delta^{-1}(v_6) = \{v_5, v_6\}$, $\delta^{-1}(v_7) = \{v_7\}$, and $\delta^{-1}(v_8) = \{v_8\}$. Let p_1 be the root of P_1 . We also have $\rho(G) = \delta(p_1)$.

Let $T = \langle t; T_1, \dots, T_k \rangle$, $G = \langle P_1, \dots, P_q \rangle$. In $\alpha(T, P_1)$, altogether five different cases as listed in Figure 9 should be checked.

Obviously, in Case (1-1), where t is a leaf node, we will check whether $\text{label}(t) = \text{label}(\delta(p_1))$ since $\delta(p_1)$ is the only left-corner which can possibly be covered by t . If it is the case, return $\langle 1, \text{parent of } \delta(p_1) \rangle$. Otherwise, return $\langle 0, \delta(p_1) \rangle$.

In Case (1-2), where $|T| > 1$, but $|T| < |P_1|$ and/or $h(t) < h(p_1)$, we will make a recursive call $A(T, \langle P_{11}, \dots, P_{1j} \rangle)$, where $\langle P_{11}, \dots, P_{1j} \rangle$ is a forest containing all the direct subtrees of p_1 . The return value of $A(T, \langle P_{11}, \dots, P_{1j} \rangle)$ is used as the return value of $\alpha(T, P_1)$. It is because in this case, T is not able to embed the whole P_1 . So we will try to find whether T is able to embed a left-corner within $\langle P_{11}, \dots, P_{1j} \rangle$.

If $|T| \geq |P_1|$ and $h(t) \geq h(p_1)$ (but $|T| \leq |P_1| + |P_2|$), we further distinguish among three cases: Case (1-3), (1-4) and (1-5).

In Case (1-3), we have $\text{label}(t) \neq \text{label}(p_1)$, and we will call $\beta(\langle T_1, \dots, T_k \rangle, \langle P_1 \rangle)$ to see whether $\beta(\langle T_1, \dots, T_k \rangle)$ is able to embed P_1 .

In Case (1-4), we have $\text{label}(t) = \text{label}(p_1)$ and p_1 is a leaf node. In this case, we return $\langle 1, p_1$'s parent $\rangle$.

In Case (1-5), we have $\text{label}(t) = \text{label}(p_1)$, but p_1 is not a leaf node. In this case, we need to call $\beta(\langle T_1, \dots, T_k \rangle, \langle P_{11}, \dots, P_{1j} \rangle)$. Assume that the return value of $\beta()$ is $\langle i, v \rangle$. We need to do an extra checking:

- If $\text{label}(t) = \text{label}(v)$ and $i = d(v)$, the return value of $A(T, G)$ is set to be $\langle 1, v$'s parent $\rangle$.

Figure 9. Different cases to be checked in α -function

- Otherwise, the return value of $\alpha(T, G)$ is the same as $\langle i, v \rangle$.

According to the above discussion, we give the following formal algorithm for the α -function (Function 5).

In Function 5, due to the use of cuts, Case (1-5) is further divided into two subcases:

1. $p_1 = v$. In this case, we will call $\beta(\langle T_1, \dots, T_k \rangle, \langle P_{11}, \dots, P_{1j} \rangle, p_{11})$ with the cut being set to be p_{11} . It is because in this case the main checking of the β -function execution may reveal that $\langle T_1, \dots, T_k \rangle$ is able to embed the whole $\langle P_{11}, \dots, P_{1j} \rangle$. In the case, the return value of $\alpha(T, G, v)$ will be set to $\langle 1, p_1 \text{'s parent} \rangle$, higher than v . So it is a useful computation; and downgrading the cut from $v = p_1$ to p_{11} will let it go through. On the other hand, p_{11} will effectively prohibit any possible further supplement checking in this β -function execution since such a checking can only bring out a left corner lower than p_{11} and will not be used.
2. $p_1 \approx v$. In this case, we will call $\beta(\langle T_1, \dots, T_k \rangle, \langle P_{11}, \dots, P_{1j} \rangle, v)$, by which v is directly transferred since we must have $p_{11} \approx v$ and

no useful computation can be eliminated by cut v .

- β -function

In comparison with the α -function, the β -function is more interesting. It is designed to handle the general Case 2. Let $F = \langle T_1, \dots, T_k \rangle$ and $G = \langle P_1, \dots, P_q \rangle$. Denote by t_l the root of T_l ($l = 1, \dots, k$). Denote by p_j the root of P_j ($j = 1, \dots, q$). In $\beta(F, G, v)$, we will make a series of calls $A(T_l, \langle P_{j_1}, \dots, P_{j_x} \rangle, v_l)$, where $l = 1, \dots, x \leq k, j_1 = 1, j_1 \leq j_2 \leq \dots \leq j_x \leq q$, controlled as follows.

1. Two index variables l, j are used to scan $T_1, \dots, T_k$ and $P_1, \dots, P_q$, respectively. (Initially, l is set to 1, and j is set to 0.) They also indicate that $\langle P_1, \dots, P_j \rangle$ has been successfully embedded in $\langle T_1, \dots, T_l \rangle$.
2. Let $\langle i_l, u_l \rangle$ be the return value of $A(T_l, \langle P_{j+1}, \dots, P_q \rangle, v_l)$. If $u_l = p_{j+1}$'s parent, set j to $j + i_l$ and v_{l+1} to p_j . Otherwise, j is not changed. Set l to $l + 1$. Go to (2) (i.e., repeat this step.)
3. The loop terminates when all T_l 's or all P_j 's are examined. (Figure 10 helps for illustration of this iteration process.)

Function 5. $\alpha(T, P1, v)$

Input: $T = \langle t; T_1, \dots, T_k \rangle, P_1 = \langle p_1; P_{11}, \dots, P_{1j} \rangle$.

Output: a left corner.

begin

```

1. if (1-1) then if label( $t$ ) = label( $\delta(p_1)$ )
2.           then return  $\langle 1, \delta(p_1) \text{'s parent} \rangle$ 
3.           else return  $\langle 0, \delta(p_1) \rangle$ ;
4. if (1-2) then return  $A(T, \langle P_{11}, \dots, P_{1j} \rangle, v)$ ;
5. if (1-3) then return  $\beta(\langle T_1, \dots, T_k \rangle, \langle P_1 \rangle, v)$ ;
6. if (1-4) then return  $\langle 1, p_1 \text{'s parent} \rangle$ 
7. if (1-5-i) then  $\langle j, u \rangle := \beta(\langle T_1, \dots, T_k \rangle, \langle P_{11}, \dots, P_{1j} \rangle, p_{11})$ 
8. if (1-5-ii) then  $\langle j, u \rangle := \beta(\langle T_1, \dots, T_k \rangle, \langle P_{11}, \dots, P_{1j} \rangle, v)$ ;
9. if  $j = d_{out}(u)$  and label( $t$ ) = label( $u$ ) then return  $\langle 1, u \text{'s parent} \rangle$  else re-
turn  $\langle j, u \rangle$ ;

```

end

Figure 10. Illustration for an execution of β -function

4. If $j > 0$ when the loop terminates, $\beta(F, G)$ returns $\langle j, p_1 \text{'s parent} \rangle$, indicating that F contains $P_1, \dots, P_j$. Otherwise, $j = 0$, indicating that even P_1 alone cannot be embedded in any T_λ ($\lambda \in \{1, \dots, \kappa\}$). However, in this case, we need to continue looking for a highest and widest left-corner $\langle i, u \rangle$ in P_1 , which can be embedded in F . This can be done as follows.

- a. Let $\langle i_1, v_1 \rangle, \dots, \langle i_k, v_k \rangle$ be the return values of $A(T_1, \langle P_1, \dots, P_q \rangle, v_1), \dots, A(T_k, \langle P_1, \dots, P_q \rangle, v_k)$, respectively. Since $j = 0$, each $v_l \in \delta^{-1}(\rho(G))(G)$ ($l = 1, \dots, k$).

If each $i_l = 0$, the return value of $\beta(F, G)$ should be $\langle 0, (G) \rangle$. Otherwise, there must be some v_l 's (higher than v) with $i_l > 0$. We call such a node a *non-zero point*. Find the first non-zero point v_f with children $w_1, \dots, w_s$ such that v_f is not a descendant of any other non-zero point. Then, we will check $\langle T_{f+1}, \dots, T_k \rangle$ against $\langle P[w_{i_f+1}], \dots, P[w_s] \rangle$. This can be done by a recursive call $\beta(\langle T_{f+1}, \dots, T_k \rangle, \langle P[w_{i_f+1}], \dots, P[w_s] \rangle)$. Let y be a number such that $\langle P[w_{i_f+1}], \dots, P[w_{i_f+1}] \rangle$ can be embedded in $\langle T_{f+1}, \dots, T_k \rangle$. The return value of $\beta(F, G)$ should be set to $\langle i_f + y, v_f \rangle$. $\square$

In the above process, (1), (2) and (3) together are referred to as a *main computation* while (4) alone as a *supplement computation*. In addition, special attention should be paid to the condition under which a supplement computation is conducted:

- $j = 0$, and
- There exists at least a non-zero point.

We refer to this condition as the *supplement checking condition* (SCC-condition for short). In terms of the above discussion, we give the following formal algorithm for the β -function (Function 6).

In Function 6, we have two *while*-loops: one from line 2 to 7 and the other from line 12 to 15. In the first *while*-loop, we do the main computation to find a largest j such that $\langle T_1, \dots, T_k \rangle$ embeds $\langle P_1, \dots, P_j \rangle$. In the second *while*-loop, the *supplement computation* will be conducted. However, this is done when the SCC-condition is satisfied.

In order to record the first non-zero point which is not a descendant of any other non-zero point, variable f is used. Initially, f is set 0. Therefore, if no non-zero point is found, we must have $f = 0$ after the main computation is completed. So only when $j = 0$ and $f > 0$, the SCC-condition is satisfied and the supplement computation will be performed (see lines 8 and 9), in which we check

Function 6. $\beta(F, G, v)$

Input: $F = \langle T_1, \dots, T_k \rangle$, $G = \langle P_1, \dots, P_q \rangle$.

Output: a left corner.

begin

```

1.       $l := 1$ ;  $j := 0$ ;  $u := v$ ;  $f := 0$ ;
2.      while ( $j < q$  and  $l \leq k$ ) do                (*main checking*)
3.           $\langle i_l, u_l \rangle := A(T_l, \langle P_{j+1}, \dots, P_q \rangle, u)$ 
4.          if ( $u_l = p_1$ 's parent and  $i_l > 0$ ) then  $\{j := j + i_l; u := p_j;\}$ 
5.          else if ( $u_l$  is an ancestor of  $u$  and  $i_l > 0$ )
6.              then  $\{u := u_l; f := l;\}$ 
7.               $l := l + 1$ ;
8.          if  $j > 0$  then return  $\langle j, p_1$ 's parent  $\rangle$ ;
9.          if  $f = 0$  then return  $\langle 0, \delta(p_1) \rangle$ ;
10.         let  $w_1, \dots, w_s$  be the children of  $u_f$ ;                (*supplement checking*)
11.          $l := f + 1$ ;  $j := i_f$ ;
12.         while ( $j < s$  and  $l \leq k$ ) do
13.              $\langle i_l, v_l \rangle := A(T_l, \langle G[w_{j+1}], \dots, G[w_s] \rangle, w_{j+1})$ ;
14.             if ( $v_l = v_f$  and  $i_l > 0$ ) then  $j := j + i_l$ ;
15.              $l := l + 1$ ;
16.         return  $\langle j, u_f \rangle$ ;

```

end

$\langle T_{f+1}, \dots, T_k \rangle$ against $\langle P[w_{i_f+1}], \dots, P[w_s] \rangle$, where $w_{i_f+1}, \dots, w_s$ are all those children of the first non-zero point v_f such that the subtrees rooted at them are not covered by $\langle T_1, \dots, T_f \rangle$. (Notice that $\langle i_f, v_f \rangle$ is the return value of $A(T_f, \langle P_1, \dots, P_q \rangle$ with $i_f > 0$.) The following example helps for illustration. In this example, we trace the execution of our basic algorithm when applied to the tree T and the forest G shown in Figure 7.

CONCLUSION

In this paper, a new algorithm is proposed to solve the ordered tree inclusion problem. Up to now, the best algorithm for this problem needs quadratic time. However, ours requires only $O(|T| \cdot \min\{h_p, |\text{leaves}(P)|\})$ time and $O(|T| + |P|)$ space, where T and P are a target and a pattern tree (forest), respectively; h_p is the height of P and $\text{leaves}(P)$ is the set containing all the leaf nodes of P . The critical

concepts of our algorithm are the *left-corner* and *cuts*, which enables us to develop a deep insight into the tree inclusion problem and extend it to a more general one to return a left corner as a result. In practice, the general problem seems to be more useful than the original one since if P cannot be embedded in T , we may want to know whether any part of P can be embedded in T . In addition, our algorithm is more efficient than any existing method for the problem by using cuts to skip over useless computations.

FUTURE WORK

In the near future, we will work on the unordered tree inclusion, by which the order of sibling is not important. According to (Kilpeläinen and Mannila, 1995), this problem is NP -complete. Therefore, our research will focus on the approximate algorithms. For example, we may relax the matching criteria to allow more than one siblings in a pattern

to be mapped to a single node in a target as long as they share the same label as done by *Twig Joins* (Chen, 2006). We can also allow *k-mismatches* as done by the string matching problem, which can be more useful for the *RNA* structure matching, and the data mining.

KEY TERMS AND DEFINITIONS

Bottom-Up Tree Search: A systematic way to explore a tree, by which a node will be visited after its children are visited.

Interval: A pair of integers $[a, b]$ where b denotes the rank of v in a post-order traversal of a trie. Here the ranks are assumed to begin with 1, and all the children of a node are assumed to

be ordered and fixed during the traversal. In addition, a denotes the lowest rank for any node u in the subtree rooted at v . Its purpose is to check the reachability. Let $[a, b]$ and $[c, d]$ be the intervals associated with v and u , respectively. If $[c, d] \subset [a, b]$, then u is reachable from v through a path in the tree.

Ordered Tree Inclusion: Mapping a pattern tree into a target tree, by which the labels and ancestor/descendant relationship, as well as left-to-right ordering of nodes should be preserved.

Top-Down Tree Search: A systematic way to explore a tree, by which a node will be visited before its children are visited.

Tree Matching: Mapping a pattern tree into target tree, by which the labels and parent/child relationship of nodes should be preserved.

Twig Matching: A kind of relaxed unordered tree inclusion, by which more than one node in a pattern can be mapped to a single node in a target as long as labels and ancestor/descendant relationship of nodes are preserved.

Unordered Tree Inclusion: A tree inclusion, by which the ordering of siblings is not important.

Information Seeking Models in the Digital Age

INTRODUCTION

Information Seeking Behavior of students in higher academic institutions is an exhaustive and complex process. The theoretical representation of such process is very difficult to comprehend, thus the graphical or pictorial representation will make things easier to understand and the same principle forms the base of Information Seeking Models. A model may be defined as a structure for thinking about a perceived problem and may evolve into a statement of the relationships among theoretical propositions. Information seeking models diagrammatically represent the complex tasks of information seeking process. Most Information Seeking Behavior models are generally the statements, often in the form of diagrams that attempt to explicate an information-seeking activity, the causes and consequences of that activity, or the relations among stages in information Seeking Behavior (Wilson, 1999). Information seeking models aim to describe the process that a user follows to satisfy his information need and while fulfilling that need, he approaches towards formal and informal information sources or available services which finally results in success or failure to retrieve desired information. A number of models have been designed by various authors and researchers from time to time globally relevant to information needs and seeking behavior of users in various academic institutions. Some models also highlight major as well as minor factors that

may directly or indirectly influence the Information Seeking Behavior of users.

BACKGROUND

Most models of information behavior are generally the statements, often in the form of diagrams that attempt to explicate an information-seeking activity, the causes and consequences of that activity, or the relations among stages in information-seeking behavior. Behavior may be defined as the more general field of investigation with information-seeking Behavior being seen as a sub-set of the field, particularly concerned with the variety of methods people employ to discover, and gain access to information resources, and information searching Behavior being defined as a sub-set of information-seeking, particularly concerned with the interactions between information user (with or without an intermediary) and computer-based information systems.. The first model for study of Information Seeking Behavior was proposed by James Krikelas in 1983. This model suggests that the steps of information seeking process are as follows:

1. Perceiving a need,
2. The search,
3. Finding the information, and
4. Using the information which results in either satisfaction or dissatisfaction.

Over the period of four decades a number of information seeking behavior models have been propounded by many researchers globally (Sawant, 2015). Robson and Robinson (2015) reveal that *Model* presents practical vision into the information seeking behavior of users and the factors that influence them. A variety of models like that of Kuhlthau, Dervin, Wilson, Ellis etc. describe the information seeking process of researchers and students thereby highlight important activities, services, actions and issues related to their information search (Infomatters, 2006). Bates (2005) reveals that *Models* are most useful at the description and prediction phases of understanding a process. Proper explanation of a phenomena results in a 'Theory'. It is believed that most of the theories in LIS are still at the modeling stage. Models are of great importance in the improvement of theory. They are a kind of proto-theory, a tentative anticipation set of associations, which can then be validated by means of various tests. McKenzie (2003) found that many information seeking models are limited in their ability to explain everyday life information seeking. These are generally related to the studies of scholars or professionals and some have been designed using a *cognitive approach* to model building. However, Robson and Robinson (2013) state that the existing models have some elements in common and most of these in the field of Library and Information Science focus on information seeking behavior of users. Nkomo (2009) divulges that scholars within Library and Information Science as well as outside the field have designed several information seeking models to sketch the information seeking behavior of researchers and students. It can therefore be supposed that the models somehow map out the development of information seeking and number of such models have been designed like *Ellis 1993 model*, *Kuhlthau's 1992 model* etc. These models have been applied by researchers to examine the information seeking behavior of various users in different academic institutions of the world (Kakai, Odongo & Bukenya, 2004).

Information Seeking Models

A number of models have been designed from time to time globally by various authors and researchers relevant to information needs and seeking behavior of users in various academic institutions. Some of the famous models of information seeking behavior are discussed as:

Models Proposed by T.D. Wilson

T.D. Wilson has put forth a series of models of Information Seeking Behavior including Wilson Model (1981), Wilson Model (1996) Wilson Model (1999) etc.

Wilson's Model (1981)

Wilson propounded an Information Seeking Behavior model in 1981 (Figure 1) in which he suggested two things:

- Information need is not a primary need rather it is a secondary need that arises out of needs of a more basic kind.
- While satisfying his information needs the user come across various problems or barriers.

Drawing upon definitions in psychology, Wilson states that the basic needs can be defined as physiological, cognitive or affective. He further reveals that the needs arise as a result of personal life issues or the environments (political, economic, technological, etc.) within which that life or work takes place. He then suggests that the barriers that hamper the information search arise as a result of satisfying those needs (Wilson, 1981).

Wilson's Model (1996)

Wilson proposed another model in 1996 as a modification to his earlier model of 1981 which presents a cycle of information activities from the rise of information need to the information use of

Figure 1. Wilson's 1981 model of information-seeking behavior (Wilson, 1981)

an information seeker. It also shows the intervening variables like (Demographical, Psychological etc.) which play a pivotal role in influencing the Information Seeking Behavior of the user. According to Wilson, it is not necessary that every need of the user lead to Information Seeking Behavior. The model identifies not only impending personal variables and modes of seeking information but also highlight relevant theories (Social learning

theory, Risk/reward theory) of motivations behind the user's search behavior.

Wilson's Model (1999)

Another, information seeking model (Figure 3) proposed by Wilson was again on 1999 which stresses on the intricacies of context of information seeking process like that of Dervin's sense making metaphor. This model of Wilson is com-

Figure 2. Wilson's (1996) model of information seeking behavior

monly known as the Macro-model. This model comprises of three important aspects viz:

- Why information seeking is more likely to occur in response to some needs more than others.
- Why some information sources are more used by the users than others.
- Why user's opinions of their own competence influences their success in meeting an information goal.

According to Wilson, as feedback of user is necessary aspect of overall information seeking process so in his model, he stresses on information process and invokes a feedback cycle in which he highlights *information seeking* as *iterative* at many steps rather than successive (Wilson, 1999).

Model Proposed by Brenda Dervin

Brenda Dervin is one of the famous Psychologists who proposed a well-known model on the cognitive dimension of Information Seeking Behavior of users. Her model (Figure 4) comprises of three important steps i.e. Situation, Gap and Use. In the model, she describes that human's progress through space and time (Situation) whereby they come across a cognitive gap which results in the creation of information need. According to her, such gaps are bridged by using the new information prior to proceeding further (Dervin, 1992).

She further extended it in the form of an important theory known as *Dervin's Sense-making Theory*.

Dervin's Sense Making Theory of 1996

Although, Brenda Dervin developed the Sense-making theory after years of efforts together and proposed it in 1996 in the form of a diagrammatic sketch as given in Figure 5 but she called it as theory rather than a model as she states it as "*a set of assumptions, a theoretic perspective, a methodological approach, a set of research methods, and a practice*" designed to handle with information perceived". She focuses on four significant aspects of user's Information Seeking Behavior viz:

- A Situation (Experience, background etc.) in space & time which determines the circumstances in which information problems arise.
- A Gap (Doubt, ambiguity etc.) which examines the difference between the contextual situation and the desired situation (e.g. ambiguity).
- An Outcome (Consequences, impact etc.) that is the result of the Sense-Making process.
- A Bridge (Ideas, Thoughts etc.) which indicates the means and the techniques used for closing the gap between situation and outcome (as cited in Wilson, 1999).

Figure 3. Wilson's model (1999) of Information Seeking Behavior (Problem Solving Model)

Figure 4. Dervin's Model

Model proposed by Carol Kuhlthau

Carol Kuhlthau's Model (1991)

Carol Kuhlthau propounded an Information Search Model (ISM) in 1991 (Figure 6) and is based on Kelly's Theory who believes that learning is a process of testing constructs. According to Kuhlthau, reduction of ambiguity and uncertainty is the basic motivator of research. She divided information seeking process into different stages. She relates each of these stages with the emotional state of researcher. For example, she relates *Anxiety* with the recognition of uncertainty at the first stage i.e. *Initiation*. The other five stages and related emo-

tional states (listed in parenthesis) are: Selection (*optimism*), Exploration (*confusion/frustration/doubt*), Formulation (*clarity*), Collection (*confidence*) and Presentation (*relief/satisfaction or disappointment*) (Kuhlthau, 1991).

Kuhlthau 'Six stages' are discussed below:

1. **Initiation:** This is the first stage of the process; expressed by feelings of uncertainty and more general thoughts with a need to be aware of or connect new to existing knowledge.
2. **Selection:** In this stage, selection of a general topic with some common feelings of hopefulness takes place in order to identify most significant areas of the topic.
3. **Exploration:** It is the third step of the process in which scrutinizing to extend personal perception and decrease the feelings of doubt and confusion about the topic takes place.
4. **Formulation:** Here the researcher focuses on the process by means of encountered information accompanied by feelings of increase in confidence.

Figure 5. Dervin's sense-making Theory (Wilson, 1999)

5. **Collection:** In the fifth stage, the researcher interacts smoothly with the information system with confidence as the topic is analyzed by selecting and evaluating information.
6. **Presentation/Closure:** It is the final stage of the process which ends the process with a sense of confidence or failure depending on how useful are the findings (As cited in Baro, Onyenania & Osaheni, 2010).

Carol Kuhlthau's Model (1992)

Kuhlthau (1992) developed another model of the ISP as a modification to her earlier model of 1991. Although, her earlier model included the feelings of the researcher with the different stages of search process but this model also encompasses the development of thoughts about a research topic, and the actions of seeking and using sources. The model goes beyond the mere mechanics of information seeking; it incorporates three realms: *the affective (feelings), the cognitive (thoughts), and the physical (actions and strategies)*. These realms are common to each stage of the search process, as described below (Figure 7).

Kuhlthau's model suggests that user is an active participant in information search process. According to her the student's knowledge grows as he interacts with the information. He uses his

cognitive behavior and cognitive strategies such as brain storming, thinking, predicting, consulting, choosing, identifying, selecting, defining and confirming. Although, the model is silent about how to convert information and data into knowledge but it highlights the affective feelings of users such as nervousness, hesitation, uncertainty, confusion, anxiety, anticipation, doubt, optimism, and confidence in the search process. This model focuses on the search process and the activities associated with finding information rather than how to use, synthesize, and evaluate the information that is found.

Model Proposed by Ellis

Ellis propounded a model (Figure 8) on the basis of studies related to the Information Seeking Behavior of social scientists, research scholars and research scientists. His model also comprises of six categories of information seeking activities viz:

1. Starting
2. Chaining
3. Browsing
4. Differentiating
5. Monitoring
6. Extracting.

Figure 6. Kuhlthau's model of the information searching process (Kuhlthau, 1991)

Figure 7. Kuhlthau's Model

Image source: <http://people.ualgary.ca/~ahayden/kuhlth.gif>

TASK	THOUGHTS	FEELINGS	ACTIONS	STRATEGIES
STAGE 1: TASK INITIATION	Contemplating assignment Considering possible topics	Apprehension Uncertainty	Talking with others Browsing library collection	Brainstorming Discussing
STAGE 2: TOPIC SELECTION	Consider personal interest, project requirements, info available, time	Confusion Anxiety Anticipation	Consulting with informal mediators Preliminary search of the library	Discussing possible topics Using general sources for overview of possible topics
STAGE 3: PREFOCUS EXPLORATION	Become informed about a general topic Seeking focus Identifying possible focuses Inability to express precise info needed	Confusion Doubt Threat Uncertainty	Locating relevant info Reading Taking notes Making bibliographic citations	Reading Intentionally seeking focus Listing descriptors
STAGE 4: FOCUS FORMULATION	Predicting outcome Using criteria of personal interest, project requirements, info available, time Identify ideas	Optimism Confidence in ability to complete task	Reading notes for themes	Making a survey of notes Listing focus Choosing focus Combining focus
STAGE 5: INFORMATION COLLECTION	Seeking info to support focus Defining and extending focus Gathering pertinent info Organizing info	Realization of amount of work to be done Confidence in ability to complete task Increased interest	Using the library Requesting specific sources Taking detailed notes	Using descriptors to find pertinent info Comprehensive searches Using indexes Requesting assistance
STAGE 6: SEARCH CLOSURE	Identifying need for additional info Consider time restrictions Diminishing relevance Exhausting resources	Sense of relief Sometimes satisfaction Sometimes disappointment	Rechecking sources Confirming info	Returning to library to make summary search Rechecking info

These activities are discussed as:

1. **Starting:** It is the first step and it consists of those activities that user carries out at the beginning of searching needed information. Here, the user selects the sources of information that are relevant to his information needs. He may be familiar with the identified sources that have been used before or unfamiliar about these depending upon his experience and knowledge. These sources also help him in finding more relevant sources by means of pointing to, suggest, or recommended additional sources or references.
2. **Chaining:** It is the second step of information search which begins after starting stage. Chaining can be either backward or forward. Backward chaining is generally carried out by researchers and scientists. Here, references from an initial source are followed. While as, forward chaining identifies and follows up on other sources that refer to an initial source or document. Although it can be an effective way of broadening a search, forward chaining is much less commonly used (Al-Muomen, Morris & Maynard, 2011).
3. **Browsing:** In this step, the user starts browsing his desired information by looking tables of contents, lists of titles, subject headings, names of organizations or persons, abstracts, conclusions and summaries etc. Here, the user browses information relevant to his needs. He uses formal as well as informal sources.
4. **Differentiating:** In the fourth step, user filters and scans the collected information by noticing the differences between the nature and quality of information offered by various sources. Experience and previous knowledge plays a significant role in this process.
5. **Monitoring:** This step deals with the activity of keeping oneself abreast with the latest developments in his specific field of study by regularly following particular sources of information. Here, the user keeps track on the Core sources which may furnish latest and relevant information to his needs. Core sources may include professional or

researcher groups, experts, authentic publications etc.

6. **Extracting:** It is the final step of Ellis Model in which the user systematically extracts the desired information from the relevant sources. The user extracts information either directly from the sources or indirectly by searching through online indexes, databases, bibliographies etc (Choo, Detlor & Turnbull, 1999).

According to Ellis, each step in his model is very important and each of these varies in according to the environment in which the user satisfies his information need. But no matter what the circumstances are, the process must start with the Starting feature, and end with the Ending. Ellis model is similar to Wilson's model to a good extent.

Comparison Between Ellis and Kuhlthau's Model

Both the Ellis as well as Kuhlthau's models discuss the overall process of Information Seeking Behavior of an individual while searching his desired information. Wilson (1999) combined the two models (Figure 9) together into one model

to easily mark the differences and similarities between the views of the two authors.

Wilson (1999) is of the opinion that though both the models have many similarities but there occurs many differences as well. According to him, Ellis model has the flexibility in its application to various situations as he states that the information behavior characteristics of an individual vary in accordance to the circumstances in which he seeks his desired information which is not seen in case of Kuhlthau's models as she has put different stages in the model on the basis of her analysis of information Behavior. So, the two models oppose. Ellis's model is more authentic compared to Kuhlthau's as it is based on experimental research and has been tested in a number of studies. One more important difference between the two models is that Kuhlthau's model includes feelings and thoughts of an individual while seeking necessary information and the way in which these thoughts and feelings gradually change as the process proceeds while as Ellis's model focuses on the logical steps that the individual takes to obtain useful information.

Thus, it can be concluded that the two models oppose in a way and match each other in another with each model examining the information seeking process from a different angle.

Figure 8. Ellis Model

Figure 9. Comparison of Ellis' and Kuhlthau's model (Wilson, 1999)

Model Proposed by Eisenberg and Berkowitz (1992)

Another model of Information Seeking Behavior was proposed by Eisenberg and Berkowitz in 1992 popularly known as Big Six Model (Figure 10) which closely resembles to that of Kuhlthau's model. This model again comprises of six logical steps and represents general approach to information problem-solving. The sequence of steps changes with different search ventures but each step is necessary for the successful resolution of an information problem.

The steps of *Big Six Skills* model are discussed as:

1. **Task Definition:** This is the first step of Big Six model. Here, an individual defines the problem or the topic about which he wants to seek information. He defines what he needs to do, what kind of information he needs to collect etc before rushing on to the strategies to retrieve information. According to Eisenberg and Berkowitz, most researchers spend very less time in understanding and defining their topic. They prefer to proceed to the next steps of information search process rather than reflecting on the type of information that they need to find. They further add
2. **Information Seeking Strategies:** This step helps in decision making i.e. the decision of selecting most appropriate and relevant sources of information among a plethora of others to get needed information. This step focuses on the methodology or the strategy to be followed to acquire the objectives of topic in hand.
3. **Location and Access:** This is one of the most important steps of Big Six Model which involves implementation of the information Seeking Strategy. It focuses on inculcating skills for using information access tools, organization of information sources in libraries, making aware about various parts of a book, use of search tools and search strategies in databases etc. Although, traditional libraries used to teach specific skills needed to use various tools to its users but the problem with teaching those skills is that users lack the understanding of how these skills can be implemented effectively in other new situations. As the Big Six Skills Model focuses on problem-solving approach so it

provides the solution by means of focusing on overall information problem-solving process rather than teaching them the skills that are restrained to a particular situation. By teaching a general problem-solving approach, the students are better equipped to utilize new and unique sources of information

4. **Use of Information:** In this step, students use information in more sophisticated and systematic way. They use skills like interacting, dialoguing, scanning, questioning, and reflecting on the information. They are able to decide what kind of information is more valuable and extract that to satisfy their information need. In Kuhlthau's Model, stage 3 and 5 are similar to as Big Six Model's step 2, 3 and 4. These all focus on finding and locating information and then using that information to satisfy desired information.
5. **Synthesis:** In this step, the extracted information is analyzed, restructured, repacked and applied in new and different form. It is sometimes applied directly like writing formulas but sometime it is also used in documenting the research articles which is a complex process and in that case it involves combining related information, reorganizing

and manipulating the gathered information. Synthesis is simply converting the collected information into knowledge.

6. **Evaluation:** It is the last step of the model in which analysis, assessment and examination of the whole information seeking process is carried out at the end. It determines the usefulness, efficiency and effectiveness of the process. This step examines whether the information found at the end related to the problem is providing real solution to the problem, satisfies the specified objectives of the topic or meets the desired information needs of researchers or the information seeker. Self-evaluation leads to lifelong information literacy of students to know their strengths and weaknesses to complete information seeking processes and can help them to take right decisions in solving such problem.

Model Proposed by Urquhart and Rowley (2007)

Urquhart and Rowley (2007) proposed a model (Figure 11) for representing the Information Seeking Behavior of students especially while accessing

Figure 10. Big Six Skills Model

Figure 11. Urquhart and Rowley Model

electronic resources of information. In their model they have highlighted *macro and micro factors* that influence the Information Seeking Behavior of students. According to Urquhart and Rowley, the *micro factors* are the factors that are related to the personality of student which includes search strategy, information literacy, pedagogy, discipline etc. The *macro factors* include information resource design, information learning technology infrastructure, organizational knowledge and culture, policies and funding etc (Urquhart and Rowley, 2007).

FUTURE RESEARCH DIRECTIONS

Models are diverse in nature including Information Seeking Behavior models and Information Search Models. The significance of these models lies in the fact that these help in understanding and examining the Information Seeking Behavior of researchers and prove beneficial to know appropriate methodologies and techniques to attain the objectives of a research problem. These help in better understanding of tasks, activities,

available services, infrastructure of universities and problems faced by users while searching for desired information thereby help administrators and higher authorities to take right decisions, offer best services, implement tech savvy infrastructure and satisfy the information needs of users especially scholars in more systematic and sophisticated way. Further, the models may also assist in examining the impact of technological advancements and information availability channels on the information seeking behavior of researchers. This study has a broader scope for future research. It can be extended to examine and highlight the information seeking behavior of Professors, Lecturers, Teachers, Post Graduate & under Graduate students associated with teaching and learning processes in different Colleges and Universities of the world. Further, research can be extended towards exploring information retrieval and information searching models.

One more area for future research is to examine the factors influencing the information seeking behavior of users in university libraries and design model for the same.

CONCLUSION AND SUGGESTION

Information seeking models diagrammatically represent the complex tasks of information seeking process. A number of information seeking models have been proposed by various authors like Wilson, Kuhlthau, Ellis etc. in different years. Most of the models comprise of many steps or stages. Models are diverse in nature including Information Seeking Behavior models and Information Search Models. The significance of these models lies in the fact that these help in understanding and examining the Information Seeking Behavior of researchers and prove beneficial to select best methodologies and techniques to attain the objectives of a research problem. These can help in better understanding of tasks, activities, available services, infrastructure of universities and problems faced by users while searching for desired information thereby help administrators and higher authorities to take right decisions, offer best services, implement tech savvy infrastructure and satisfy the information needs of users especially students and scholars in more systematic and sophisticated way. Further, it is also concluded that the models assist in comprehending all the aspects associated with the information seeking process that may be emotional, cognitive or practical. These form a foundation and provide a framework for novel researchers to design and implement new models of Information Seeking Behavior of users in their respective organizations or institutions to improve the services; facilitate authentic and relevant information resources and to eliminate all the problems and issues that users face while searching for desired information.

KEY TERMS AND DEFINITIONS

Information Behavior: Information behavior refers to how people approach and handle information.

Information Literacy: The ability to know when there is a need for information, to be able to identify, locate, evaluate, and effectively use that information for the issue or problem at hand.

Information Need: The perception of a lack of information that provokes one to develop a need for it.

Information Seeking Behavior: A special case of problem solving which, includes recognizing and interpreting the information problem, establishing a plan of search, conducting the search, evaluating the results, and if necessary, iterating through the process again.

Model: A model may be defined as a structure for thinking about a perceived problem and may evolve into a statement of the relationships among theoretical propositions.

An Insight Into Deep Learning Architectures

INTRODUCTION

For molding the world to incredible amplitude, appropriate learning of computers has inevitable participation. This ability of the computer of deploying the world can be referred as intelligence. For making a machine intelligent, it has to go through a series of training processes where the information is stored in an organized way making it easier to relate the so gathered information with the real life scenarios. Storing all the information in the machine manually is a troublesome task, especially when the information is abundant like in the case of sophisticated artificial intelligence tasks. This is why the learning algorithms have gained attention among researches to store huge information at a stretch. Many learning algorithms are established and capable of understanding the view, but failed to express efficiently in natural language. Semantic understanding of these algorithms was restricted by some degree which is the necessity and should be expanded. So it was figured out that the prior algorithms were incapable of maintaining the interaction towards the humans through various semantic and visual mediums. To resolve this problem of AI task, Deep architectures were introduced, so that the machines can be trained and can be made efficient in the areas they are lacking.

Information retrieval have widely classified into two subdivisions: image retrieval and the text retrieval (A.G. Abby, 2000). Both approaches were emerged in the mid 60-70's. In order to carry out the several tasks like indexing, searching and retrieval data has to be well organized. In this work, the focus is on the image retrieval perspective. Image retrieval is divided into query or text based and content based approach (P.A. Vikhar, 2010). Our investigation is centralized around the first methodology. Text based image retrieval is basic and fundamental one which makes use of searching through simple query word (T. Westerveld., J.C Gemert., R. Cornacchia., D Hiemstra., A. P. Vries 2005). Earlier work to this text based approach was database management systems which binds the images with text. Multi-dimensional indexing, data modeling and query evaluation are the exemplary research lines. But the fore mentioned procedures turned out ineffectual for the complex data link structures, language pairs, sophisticated image data characteristics, question answering, annotation and context retrieval. These made a way to design a new approach that addresses the various issues.

The basic question found out while natural language processing is "Is there exists any analog program loaded in computer which converts a portion of textual data represented in English into a

computer understandable data model that clearly depict the actual text meaning?”. While taking care of this problem, computer specialists have to get down for fewer objectives that represent lesser aspects of text data. Natural language processing is a flexible architecture which focuses on learning representations useful for the specific tasks. The NLP had evolved in a way for seeking a model which converts human understandable language (English in the beginning) into a machine friendly data representation that conveys the meaning of text without any ambiguity. The earlier times the evolutionary idea behind the NLP seemed to be very broad and vast for the researchers so they settled down for lesser goals of representing limited textual information by extracting simpler representations. Text processing in natural language processing encompasses by bag-of-words, removal of frequent words from the input text query (stop words), identifying the root words (stemming), spell check, text and controlled vocabulary mapping and named entity recognition.

BACKGROUND

The concept of neural networks derived from the human nervous system by the way of answering to a question which seems to be simple yet more complex while approaching “can a computer mimic the human nervous system?”. Human brain is highly complex nonlinear parallel computer. Structural constituents of human brain are known as neurons which are interconnected in complex way (Lee, T.S., Mumford, D.2003). The task of recognition through a neural network achieved by teaching the computer what to do in each and every step with a set of pre-defined procedures that is it is more like if a computer has to identify a photograph first it has to be taught by feeding various photographs then it go for a matching with the original photograph with the ones which it stores in the large database repository. It gives out the picture which carries a best resemblance with original one. While answering to the ques-

tion another constraint researchers faced is human brain processing speed which is of 10^{-3} s where as a silicon IC response time is 10^{-9} s.

The evolution of the deep machine learning starts from convolutional neural networks, deep neural networks and deep belief networks eras. Convolutional neural networks are a kind of special multi- layer neural networks which are inspired from biology. It is similar to other neural networks and they are trained with a version of back propagation algorithm but only differ in the architecture. CNN are mainly designed to recognize visual patterns directly from pixel images with minimal preprocessing. The hurdles faced by feed forward neural networks towards image processing could be resolved by the entry of CNN to some extent. The major constraint that normal FFNN facing was the rapidly growing weights with the dimensionality of the input, since every object in one unit is connected to every object in next unit. That makes it slow in learning for high dimensional domain of vision. Learning to recognize an object wouldn't even propagate the same object presented in different visual field, it's because the every pair of neurons between different units has separate weights which would be involved in the calculation. A CNN comprises of various convolutional and sub sampling layers alternatively took after by completely joined layers. The input to a convolutional layer is an $m \times m \times r$ picture where m is the tallness and width of the picture and r is the quantity of channels, e.g. a RGB picture has $r=3$. The convolutional layer will have k layers (or portions) of size $n \times n \times q$ where n is littler than the measurement of the picture and q can either be the same as the quantity of layers or littler and may shift for every part. The measure of the channels offers ascend to the generally joined structure which are each convolved with the picture to create k highlight maps of size $m-n+1$. Every guide is then sub sampled ordinarily with mean or max pooling over $p \times p$ adjoining districts where p ranges between 2 for little pictures (e.g. MNIST) and is normally not more than 5 for bigger inputs. Either before or

after the sub sampling layer an added substance predisposition and sigmoidal nonlinearity is connected to every component map.

As a solution to this architecture, conventional neural networks came, which takes the input from two dimensional spaces and should reduce the number of parameters involved in the training. Convolutional neural networks can be best explained with an experiment made in cat's visual cortex. Vann leclun and toshua bengio are two scientists who tried to understand the organization of visual cortex of cat which has complex cell arrangement. These cells are called receptive field which is very sensitive to small regions of input space and it is tiled in a fashion that would cover the entire visual field. These cells are like filters which are local to input space and it helps in the strong local correlation of the input image. In addition to that cells has been divided into two, simple cells which is used to respond to edge like stimulus patterns and complex cells which have larger receptive fields, invariant to the exact position of stimulus. Till now visual cortex is considered as the most powerful vision system.

Generally images are composed of large number of variables called pixels. A fully connected network with hundreds of hidden layers will have several tens of thousands of weights. This requires larger training set and high memory requirements which rule out certain hardware implementation. The basic problems with these unstructured nets are they don't have a built in invariance to the distortions and translations for images on speech inputs. Moreover, the input to the fixed size neural network should be size normalized and centered in the input field. The input can be character images, other 2-D, 1-D signals but there is no such preprocessing is perfect. As an example, hand written characters which can be normalized at word level causing variations with respect to size, slant and position of individual characters. Apart from that it also differs according to the writing style. These combined variations cause variations in the position of distinctive features in input objects.

In general, a fully connected network with fixed size have the capability to produce output by learning the inputs those are invariant with respect to such variations where as convolutional neural network are invariant to shift operation. Another drawback of a fully connected neural network is that it doesn't give importance to the local structure of the input. For e.g., images which have strong 2-D topology where nearby pixels are highly correlated. In CNN, local extraction of features is done by making the receptive field of hidden layers to be local.

MAIN FOCUS OF THE ARTICLE

Issues, Controversies, Problems

Indeed, the shortcomings of CNN paved a way for newer deep neural network architecture. For learning the complex functions equipped with high level abstractions which is employed in various AI task, we requisite deep architectures (B.Yoshua 2009). Deep architecture can depict the multiple levels of nonlinear data. After that the era of deep neural networks came. As the image retrieval being one of the tedious tasks the learning from an image makes its complexity a one level higher. This is where deep architecture methodology comes into existence. Prior to image retrieval an image has to be learned since learning phase comprises of various feature learning activities. Deep neural network is one such technique which involves learning from low level features of the image to more detailed high level features.

These features are deeply influenced by some factors which every image possesses such as orientation, lightning, position. These can be referred as the factors of variation. Explicit knowledge about this factors and making a relationship with the interaction patterns of these factor make the deep neural network to recreate the scene. In structural point of view deep neural network consists of multiple numbers of deep layers having nonlinear

operations. Each deep layer itself comprises of more abstracted operations. This series of hidden layers placed between the input layer and output layer enables sharing and reusing of information by applying training over these layers. Here training and learning comes along the two processes are very different. The training function is the overall algorithm that is used to train the neural network to recognize a certain input and map it to an output. A common example is back propagation and its many variations and weight/bias training. A learning function deals with individual weights and thresholds and decides how those would be manipulated. These usually (but not always) employ some form of gradient descent. The more the number of such intermediate layers the more features can be learned. In our proposed work we mainly focused our attention towards deep neural network for learning from the features at various layers. The ability of deep neural network to employ learning at each and every layer makes our model much intelligent.

Feature learning is the one of the classical problems in machine learning. In our model we utilized the idea of feature fusion from the different latent features. In contrast to the learning from features the designed method supports latent feature learning. Deep neural network strengthen the task of learning by applying the feature fusion from low level features to higher level features. DNN and DBN are two methodologies that well address the deep learning problem. The approach we are designed can be extended to any domain where feature learning and natural language processing becomes a vital part. A good citation to this can be social media where the data possess diverse, heterogeneity, noise and interconnectedness. Also DNNs relates to over fitting as the result of addition of layers of abstraction, which allow them to project rare dependencies in the training data. This led the way to DBN's evolutions.

Deep Belief Network

The other type of deep neural network is deep belief network (G.E Hinton, 2006). It includes unsupervised layer wise pre training similarly like in a deep feed forward network. DBN is unsupervised generative model which mix the directed and undirected interactions between the variables that consist of input layer or hidden layer. The top two layers always form a Restricted Boltzmann machine with undirected interactions and other layers form the directed interactions with Bayesian network. The DBN is not a feed forward neural network.

$$P(x, h^1, \dots, h^l) = P(h^l) \left(\prod_{k=1}^{l-1} P(h^k | h^{k+1}) \right) P(x | h^1) \quad (1)$$

In 1 it depicts the architecture for the deep belief network. The above equation has 1 layer with joint distribution between joint hidden layers h^k and vector x . $P(h^{l-1}, h^l)$ is the joint distribution in the top layer of restricted Boltzmann machine, here x corresponds to lowest level of the hidden layer that is h_0 and $P(h^{k-1} | h^k)$ is the visible joint distribution associated with Restricted Boltzmann machine at the level k of the DBN $P(h^k | h^{k+1})$ forms the Restricted Boltzmann machine.

We can show in 1 a generalize model with consist of three hidden layer. The full distribution of the deep belief network with three hidden layers is given below.

$$P(x, h^{(1)}, h^{(2)}, h^{(3)}) = P(h^{(2)}, h^{(3)}) P(h^{(1)} | h^{(2)}) P(x | h^{(1)}) \quad (2)$$

$$P(h^{(2)}, h^{(3)}) = \exp \left(h^{(2)\top} W^{(3)} h^{(3)} + b^{(2)\top} h^{(2)} + b^{(3)\top} h^{(3)} \right) / Z \quad (2.1)$$

$$P(h^{(1)}, h^{(2)}) = \pi_j P(h_j^{(1)}, h_j^{(2)}) \quad (2.2)$$

$$P(x, h^{(1)}) = \pi_i P(x_i, h_i^{(1)}) \quad (2.3)$$

Figure 1. Deep Belief Network

In 2, $P(x, h^{(1)}, h^{(2)}, h^{(3)})$ is the joint distribution over the input layer (x) and the hidden layers are (h^1, h^2, h^3). The distribution over $P(h^{(2)}, h^{(3)})$ is given by 2.1. here $P(h^{(1)} | h^{(2)})$ is the distribution of $h^{(1)}$ given by $h^{(2)}$, it doesn't depend on $h^{(3)}$, same with the other hidden and input layers. $W^{(3)}$ and $b^{(3)}$ is the weight and bias of the nodes in the third layer. Now in this kind of the network the training procedure starts with the pertaining of the top layer that is the restricted Boltzmann machine and then training the layer preceding it, this idea of initialization has formed the stacking mechanism in the DBN. A good initialization can play a crucial role in training the DBN. Otherwise training of deep belief network is the hardest.

Restricted Boltzmann Machine

The new type of neural network for unsupervised learning is Restricted Boltzmann machine (Le Roux, N., Bengio, Y, 2008). A restricted/layered Boltzmann machine (RBM) has either bit or scalar node values, an array for each layer, and between those are scalar values potentially for every pair of nodes one from each layer and an adjacent layer. The unsupervised learning only uses the inputs $x^{(i)}$ for learning and automatically extracts useful information from our data. RBM is the non-directed graphical model that finds the distribution over input vector ' x ' using the hidden layer binary inputs. ' W ' represents the connections between the visible layer and the hidden layers.

Here 'x' and 'h' are the random variables. In (3) the energy function can be calculated which on making exponential gives the distribution over the networks shown in 3.1. Here Z is a partial function which is intractable.

Energy function:

$$E(x, h) = b' - x - c'h - h'Wx \quad (3)$$

Distribution:

$$P(x, h) = \exp(-E(x, h)) / Z \quad (3.1)$$

SOLUTIONS AND RECOMMENDATION

As keeping in mind various constraints for the learning the latent features especially from an image the authors have proposed a novel technique. The proposed algorithm is capable of retrieving images with 'n' keywords, minimum of 'n' image data classes and 'n' context classes. Any NLP query can be the input to this algorithm. Then the query undergoes some pre-processing methodologies and the refined (Query, Keyword) pair is fed as an input to deep belief network. The pre-processing on query involves removing the frequently used words i.e., stop words, suffix stripping (M.F Porter, 1980) for yielding the root words, and spell check (Victoria J. Hodge, Austin Jim, 2001) to identify grammatical errors. The (Query, Keyword) pair extraction is followed by the pre-processing step. This (Query, Keyword) pair (q', K) serves as the input to first layer of deep belief network.

Numerous relations exist between the pairs and among them semantically correct pairs are extracted. Thus the relation score and semantic score can be treated as input to the successive layers of DBN. Ultimately the deep belief network points to the well-defined context classes. Fuzzy decision making approaches can aid in the mapping between the context classes and the data set for image retrieval.

FUTURE RESEARCH DIRECTIONS

Deep architectures are a promising research area, which yield more researchers to add on assorted techniques with an improved performance in the training, learning tasks. Future enhancement to this work can incorporate multi-modality to latent feature learning alongside selecting the adaptive kernel function automatically for learning through deep belief network.

CONCLUSION

The deep learning architectures are the paradigm shift in the study of artificial neural networks that evolved with an objective of optimizing the training task. The deep complex non linear structure makes this model to understand diverse latent features through various learning methodologies. This article lightens the way towards the deep architecture in the several domains. The innovative methodology depicted in this work for image retrieval aids the characteristics of natural language processing built under utilizing the deep belief network concepts. The NLP query is ensemble into various latent query features and fed into deep belief network as inputs. The proposed learning strategy makes use of restricted Boltzmann machine. After consecutive learning extract the image classes thereby retrieve the images of the analogous query.

KEY TERMS AND DEFINITIONS

Convolutional Neural Networks: A multi layer neural network similar to artificial neural networks only differs in its architecture and mainly built to recognize visual patterns from image pixels.

Deep Architectures: The deep learning architectures model higher level abstractions of data by learning through the complex abstract features embedded in the data with the help of its deep complex architecture.

Deep Belief Network: It is the type of deep neural network which is an unsupervised generative model.

Deep Neural Networks: An artificial neural network with multiple hidden processing neurons possessing higher performance in learning tasks utilizing its non linear complex architecture with the aid of back propagation algorithm. It is a model that recreates a picture by making relationships among feature of data.

Information Retrieval: The process of bringing down to the relevant information from various information resources and it can be of text retrieval, image retrieval etc.

Latent Query Features: The hidden semantic meaning of the input query such as antonyms, synonyms, homonym and polysemy.

Online Information Retrieval Systems Trending From Evolutionary to Revolutionary Approach

INTRODUCTION

Information has been available since the evolution of the world and is being applied every day. McCreddie and Rice (1999) summarize the concept of information that has been proposed over the years in various studies and explains information in four different ways. Firstly, as a representation of knowledge, studies are of the opinion that information is a representation of knowledge. Earlier when there was no concept of internet and digital media, the printed documents were assumed to be the primary representation of information. But with the advent of ICT, this view point has changed from print to the electronic media (Lievrouw, 1988). Secondly, as a data available in the environment, some of the researchers view information in broader paradigms which may include objects, sounds, smells, events, activities, artefacts, even any phenomenon of nature, etc. The data may not convey any message as such but can be informative if interpreted appropriately (Buckland, 1990; Taylor, 1991). Thirdly, as a part of communication process. Various researchers tend to believe that information is a part of communication process among individuals of the society. Social elements play vital role in processing and inferring the information which are not treated as physical or cognitive activities apart from the work of individuals but regular intrinsic activities which constitute the very nature of people while interacting in organizations (Atwood & Dervin,

1982; Solomon, 1997a; Solomon, 1997b; Solomon, 1997c). Lastly, as a resource or commodity. Some researchers stress upon information being a resource or a thing which can be generated, acquired, replicated, disseminated, employed, organised, traded, sold and exchanged. It is transmitted from a sender to receiver in the form of a message and is later interpreted at the receiving end (Arrow, 1979; Bates, 1988; Buckland, 1991; Hirschleifer & Riley, 1992). But all this makes sense to end user if this information is retrieved and received at right time with minimum of fuss and intricacies. That is where concept of information retrieval system comes to play its role, more so in cyberage when zillions of terabytes of information is generated every year.

Man by its intrinsic curiosity to gain new insights of himself and surroundings has always been on the path to search and sift whatever satisfies his intellectual quest. Every time he searches for some specific information, he draws strategy in mind to retrieve the desired information. Nowadays in order to retrieve the desired information one must have good knowhow of search mechanism. It all started at the fade end of the 20th century, with the invention of the World Wide Web that revolutionized the whole world and with this followed the exponential growth of information. Information seeking was already the basic nature of a man, and now two decades later, it has become a part and parcel of our day to day lives. The trend of information search via the traditional library

DOI: 10.4018/978-1-5225-2255-3.ch394

environments has been entirely evolved over the years to a virtual space called Web, where all this information can exist. Web contains all sorts of digitized as well as born digital formats of information which are just a click away from the users. With each passing day, World Wide Web gained popularity, thus searching through the web, also referred to as the information retrieval on the web, has become an important research area.

The Web has the features of being an information space having free access with no particular focal point to control and scrutinize the dissemination of information resulting in many challenges including the maintenance of authenticity and quality of information. Thus, various computational tools are being used in order to perform the search processes over the web among which the most widely adopted approaches are web directory and search engine services. In a web directory, the data in the web is organized in a classified manner having some hierarchical structure making it equivalent to the traditional library system. Search engines, on the other hand, are simply the web portals used to find information on the web. These have the capability of indexing large segments of the web and then storing the information in their databases. In contrast to a web directory, the processes of a search engine are carried out automatically (Zhu, 2011). Apart from web directories and search engines, there are a number of information retrieval tools that have evolved over the years revolutionizing the concept of information retrieval. In this perspective, the present study delves deep and highlight various trends in online information retrieval from primitive to modern ones. Furthermore, the study has made an attempt to visualize the future requirements and expectation keeping in view the ever-increasing dependence on diverse species of information retrieval tools.

BACKGROUND

The evolution of man has begun millions of years ago. With this, information has also evolved right from the beginning. This information has passed on to generation after generation with so many advancements through its way. Primitive man may not have farsighted the importance of storing this information, but with time it started getting clear for him that unaided memory, actions and speech cannot be sufficient to recapitulate all the information and transmit the same to future generations. Consequently, he started storing this information with whatever source he could get hold on, e.g. stones, leaves, parchments, clay tablets, wax tablets, etc. Historians and anthropologists make this advancement of primitive man evident from various live examples available even to this date like cave paintings, pictographic and hieroglyphic forms of writing, primitive sculptures, etc. Most of these storage media have flaws of deterioration in one way or the other making it obvious for people to search for other ways of storing information that could last long. Subsequently, Egyptians came up with the idea of stalks of papyrus plant pounded flat and pressed into a relatively acceptable writing surface, resulting in the existence of long strips of stalks that could be rolled. These scrolls thus became one such early forms where information could be stored. But it was difficult to locate a particular piece of information from such long scrolls. A great technical development of information storage on scrolls came when these long scrolls were cut and bound together in the form of what we today call as a 'book'. The early set up of holding the stored information was not much of a problem to organize as it was only confined to a limited stock and keepers of this information were thoroughly familiar with its entire content. This stood true only upto the invention of printing press in 16th century which revolutionized the concept of information production. This great invention enabled man to create new records with far better pace than the manual approach and duplicate the same in ample quantity. This

eventually led to the concept of organizing and managing the information that has been gathered over the centuries (Gull, 1955).

With information storage came the concept of information retrieval. Few American scientists thought of this concept after World War II for better ways to handle scientific knowledge as much of this important knowledge was being lost due to poor handling of overwhelming information in scientific literature. Though the concept of information retrieval was originally intended for scientific literature, it is applied to all the available information throughout the globe. The credit for development of information retrieval systems goes to the prophetic article "As we may think" by Vannevar Bush in 1945 where he proposed the invention of a special machine "MEMEX" to accommodate the records in the form of a microfilm. According to Bush, the machine was easy to build but designing a workable indexing system was the real problem to face (Wilds, 1961).

The notion of information retrieval has been a problem ever since man started saving his thoughts and surrounding information he became aware of. However, the concept of 'Information Retrieval' was already prevailing in the scholarly community but was unknown until Calvin Mooers coined the term in early 1950s. While reviewing the previous literature, it has been observed that there is a variation in the exact year when the term was actually coined. Studies claim that the term was coined in 1949 (Fairthorne, 1968), some say in 1950 (Mishra, 2014), some in 1951 (Hjørland, 2006), while some are of the opinion that the term was coined in 1952 (Onwuchekwa & Jegede, 2011; Sparck & Willet, 1997).

Information retrieval refers to the area of study that deals with searching for documents, information available in the documents, structured databases like digital libraries, or web and retrieving the relevant information to the users for their use. It is an interdisciplinary field based on information science, computer science and cognitive psychology. The basic goal of information retrieval was to create such systems (for instance,

bibliographic databases) which could provide access to a number of information resources like books, journals, etc. Now-a-days, the most visible information retrieval applications are web search engines (Dineta, Chevalierb & Tricot, 2012).

TRENDS IN INFORMATION RETRIEVAL SYSTEMS

1. Indexing Approach

Mooers (1960), though being the one to coin the term himself, after a decade has the notion that there are yet no complete solutions for retrieval of large collections of information. At that time, information retrieval was not regarded as the sheer discovery and providing information.

Arnold (1958) on the other hand gives an overview of previous ten years about various aspects in the field of information retrieval. The study shows that over the past decade, researchers have been concerned with different possibilities of improving how information can be stored in catalogues and how to prepare an exhaustive list of entry points for an index so that effectiveness could be achieved in the process of information retrieval. The researchers working on index formation have been inspired by Mortimer Taube's Uniterm indexing system. Besides Taube, with the help of Batten's punched card system, introduced his method of referring a user to the relevant information based on previous research works.

Studies have revealed that evolution of information retrieval systems started with various retrieval tools like card catalogues, indexes, etc. (Shaw, 1951; Voigt, 1956).

There have been many types of card catalogs that are observed to be used for early information retrieval purposes. Edge-notched cards (also known as edge-punched cards) being one of earlier tools used where all indexing characteristics of one particular record are punched at one place or card. Another type of card is aspect card which include Uniterm card, Peek-a-boo card, Batten card, etc.

Here, each characteristic of an index is recorded separately. One more form of card catalogs include punched cards (also called Hollerith cards). These punched cards are similar to edge-notched cards except that machines are involved while searching and thus a large number of index entries can be expected (Wilds, 1961).

Gull (1955) speaks about punched card accounting machines which needed human supervision so that information could be organized, stored and later retrieved. Thus, analog and digital computers have been given preference which can operate on large amounts of information utilizing minimum possible time. These computers could also be used with lesser human supervision for many hours when programmed accurately.

Moreover, Dietrich (1960) while studying about machine retrieval of Pharmacological data has been of the opinion that punched cards along with machine sorting can be helpful in organizing and retrieving the Pharmacological data.

Kendrick (1964) studies about information storage and retrieval revealing that punched cards are being used which helped for machine sorting, print outs, etc. and eventually magnetic tapes, discs or drum storage would help simplifying the practical applicability of various integrated systems of electronic information storage and retrieval once those are introduced.

Taube (1956) in his study discusses about the machine retrieval and makes it clear that machine retrieval at that time was not as satisfactory as retrieval using tools like card catalogs or to be precise, printed cards. He further says that even though card catalogs show better results than machine retrieval but at the same time these card systems do not fit for large scale storage and retrieval systems.

2. Computer-Based Approach

The emergence of computerized information retrieval services began in early 1970's. Since then, a number of information retrieval services have appeared while a decade later, indexing and

abstracting services started gaining importance in the field of information retrieval. Some of these services include Educational Resources Information Center (ERIC), National Information Center for Educational Media (NICEM), Exceptional Child Educational Resources (ECER), etc. Such information retrieval services help in an efficient and rapid retrieval of information. Searching via ERIC is boosted by using its controlled vocabulary "*Thesaurus of ERIC Descriptors*". Apart from this, users can use keywords from title or abstracts which may act as additional access points for searching thus increasing the efficiency of searching (which cannot be seen in manual searching). Search strategy modifications like broadening, limiting, or refining the search yield more relevant search results, again increasing the efficiency of retrieval systems (Gerke, 1981).

Computer-based information retrieval systems have grown to the full bloom in late 1970s and early 1980s. Bawden (1984) thus talks about the use of various indexing and abstracting services for Statistical Literature. The study shows a trend of using various indexing and abstracting services (like Index Medicus, Science Citation Index, Mathematical Reviews, Statistical Theory and Method Abstracts, etc.) during the present decade for an efficient retrieval of relevant information.

Indexing, abstracting, thesauri formation, file formatting, etc. have always been the topics of interest for researchers in the field of library and information science. With the advent of high speed computers, and a simultaneous interest in the field of information retrieval, the latest trend is directed towards assessing the effectiveness of various computerized file structures and search strategies besides, comparing the utility of index languages as well (Levine, 1985).

According to Salton (1991), the records stored in information retrieval systems during this era are typically identified by using Boolean combinations of index terms. The retrieval systems are designed in a way that provide only those results which match the exact combinations used in search queries.

Figure 1. Rough timeline of the generations of information retrieval in digital libraries. Source (Schatz, 1997)

3. Bibliographic Databases Approach

Early 1970s witnesses the development of on-line systems allowing interactive searching. These online systems thus paved way to the development of various bibliographic databases for information retrieval which can hold information about millions of records. These online information retrieval systems used inverted file organization and also incorporated various search techniques like Boolean operators, truncation, etc. helping users formulate their queries in a better possible way and retrieve better results (Salton, 1980).

Doszkocs, Rapp and Schoolman (1980) in their study talk about the development of simple retrieval systems based on the use of natural language which can be achieved by dealing with the ambiguities of syntax and grammar. It has been seen from the recent studies about National Library of Medicine that various prototypes using English language interface have been developed, e.g. MEDLINE, Hepatitis Knowledge Base, TOX-LINE, etc. The basis for the development of such prototypes was a change from complex retrieval systems to simple ones using natural language of users and understanding that language in order to provide relevant results to the query.

Leider (1964) discusses about microfilm retrieval system whose concept was envisioned by Vannevar Bush in his visionary article regarding Memex. Records can be saved in miniaturized

forms in microfilms. In this context, Leider says that microfilm retrieval systems not only list the document numbers but provide full text records about a particular information which can be reproduced in the form of hard copies later by users.

4. Web Based Approach

Right from the development of online information retrieval era, the fundamental functions involved in information storage and retrieval processes had not changed for over three decades but Schatz (1997) has envisioned fundamental technology for large collection retrieval changing for future generations from syntactic to semantic approach. Figure 1 shows the Grand vision proposed by Schatz. Schatz further says that the recent advances in World Wide Web (WWW) has enabled users of online information retrieval systems to search for information sources across the global network with the help of internet.

Xie and Cool (1998), Ahmed et al. (2005), Islam and Panda (2007) provide a scenario of emerging interactive information retrieval systems offering sophisticated system features such as use of natural language queries, rank documents as per relevancy, automatic relevance feedback, provide full text of documents, etc. Furthermore, Xie and Cool (1998) give emphasis on another emerging concept of web based searching as is it intrinsically interactive providing various significant

Figure 2. Semantic web architecture. Source: (Thangaraj & Sujatha, 2014)

features like navigation to different databases, use of multiple interactive search strategies, mapping to thesaurus terms, etc.

Chowdhury (1999) also emphasizes on the significance of World Wide Web which led to the use of internet for information exchange in all spheres of day to day life. Libraries started offering various services via internet like Online Public Access Catalog (OPAC), online databases vendors like DIALOG, and CDROM database vendors like SilverPlatter, etc.

Ide and Salton (1971) while studying about interactive search strategies in information retrieval predict that retrieval effectiveness can be achieved more significantly by adopting adaptive interaction techniques which would help in extracting information from users thus improving the organization of data space. Hence leading to better and effective search and retrieval processes.

5. Semantic Approach

The concept of semantic search in the field of information retrieval though has been available since early 1980s (Croft, 1986; Guarino et al., 1999), but could not gain much importance until Berners-Lee proposed the concept of semantic web technology in 2000 who defines it as an extension of web where information is given a well-defined meaning assisting users and information retrieval systems to work in cooperation with each other (Berners-Lee, Hendler & Lassila, 2001; Lou & Qiu, 2014).

Figure 2 shows the architecture of semantic web as proposed by Berners-Lee. The main objectives of semantic web include semantic query processing and finding semantic information from unstructured information available on the web (Thangaraj & Sujatha, 2014).

Since the architecture suggested by Tim Berners-Lee in 2000, various studies have been carried out proposing structural layouts of semantic web. Ilyas et al. (2004) has suggested a conceptual architecture for semantic search engines laying main emphasis on inference engine. This model

has been created using a complete knowledge base using a relational database and claiming that the model shows high performance as data can be directly retrieved from the knowledge base reducing the noise to the maximum level. Later in 2007, Zhi-Qiang et al. (2007) proposes another framework of semantic web search engine based on domain ontology. This architecture is based on a crawling mechanism as seen in present day search engines like Google, Bing, etc. and uses an already constructed ontology based information extraction algorithm to retrieve information from crawled web pages.

Fernández et al. (2011), Kara et al. (2012) talk about the advances in information retrieval from contemporary keyword approach to conceptualization approach (i.e. semantic approach) as semantic approach has been in its evolution phase at the time of these studies. Renl (2009) also discusses more advanced areas of information retrieval focusing on emerging three areas viz. cross-lingual, multimedia and semantic-based information retrieval. Firstly, cross-lingual approach involves the retrieval of information in more than one language. The resulting information can be later translated into the language of user query so that users may understand the gist of retrieved document. This approach became necessary with increasingly globalized economy. Secondly, apart from finding different types of media on internet, various information storage systems like computers started being used to store this media other than text such as audio, video, images, etc. and thus methods for rapid and accurate retrieval of such media also became a necessity resulting in multimedia information retrieval. Finally semantic information retrieval tries to go beyond the traditional approach of retrieval and is based on concept based approach i.e. it tries to define concepts in documents and queries rather than just focusing on query terms, thus aids in improved and efficient retrieval of information.

Bodoff (2006) while discussing about the conventional information retrieval interfaces (i.e. the last decade of 20th century and the beginning of

21st century) says that these interfaces have been designed for analytical approach of searching rather than just a browsing approach, the web based interfaces otherwise involve browsing approach.

Traditional information retrieval systems lead to low precision and high recall. However, in case of semantic based information retrieval systems, an improvement in the relevancy of retrieved results is observed as these systems understand the search intentions and conceptual meaning of queries entered by users (Remi & Varghese, 2015).

To crown it all it would be in the fitness of things to shed some light on Google - the most popular search engine, and the first preference for most of the online users when it comes to searching information on World Wide Web, a detailed account of Google and its searching mechanism is given as follows:

Google Search, owned by Google Inc., is commonly referred to as Google Web Search or simply Google. It is the most widely used search engine managing more than three billion searches per day. It is also ranked as the most used search engine in the United States as of September 2016. Google is commercial web search engine and is available in 123 different languages, thus having multilingual interface.

Google Search Mechanism

When users submit any search term in Google search, a very long list of mostly relevant search results (often in millions) from all over the web is presented to them instantly. There are three main processes that Google search undergoes while performing the search and delivering the results:

Crawling

Crawling when defined is simply a process in which Google index is generated by adding new and updated pages with the help of Googlebot. Googlebot is a computer program that is used to fetch hundreds and thousands of web pages in order to create an index called Google index. Googlebot

is many a times synonymously used for spider, robot, or simply bot. The algorithmic process used by Googlebot is that the program first determines which sites need to be crawled, how often these sites need to be crawled, and finally how many pages need to be crawled from each site.

The crawling process in Google starts with previously created list of web page URLs and eventually the list is increased with recently uploaded web pages by various data providers. Googlebot keeps on detecting links on every site and adding the same to the index. Whenever any new site, any change in previous site, or any dead link is detected, it eventually updates the Google index in order to keep it up to date.

Indexing

After crawling any page, Googlebot processes that page so that an index can be compiled from all the words in that page along with the location of each word on the page. It further includes all the information in key content tags and attributes in the index. It is important to note that Googlebot has the ability to process most of the content types except for few like some rich media files.

Serving Results

This process is concerned with the communication between the system and the user. This process starts when a user submits any query and ends with displaying the results to the users. After the submission of a search query, the system searches its index for related information and tries to return back the most relevant results to the user. This relevancy is determined by so many factors, and PageRank is one such factor. Page rank (named after one of the founders of Google, Larry Page) is an algorithm which ranks websites by determining their importance for a search query. This is done by counting how many links are associated with a particular website or page and how qualitative these links are, thus determining the importance of that particular page i.e. more the

links associated to a page, more is the importance of that page. All the factors that negatively affect the search results like spam links are always kept in check by Google so that user experience can be constantly improved. Google is trying hard to make its interface more user-friendly and some features like “Did you mean” and Google Autocomplete (Stemming) are best examples to explain the same. Since the time of the user is very important (Ranganathan’s Fourth Law of Library Science), Google has designed these features to help users save their time by displaying popular queries, related terms, or even common spelling errors (Google, 2015).

However, the trend is changing from having robust search mechanism to personalized information delivery service based on previous search behavior of the user what we also call in our parlance proactive or anticipatory service. Such trend is fast picking up and is adapted and developed by most of the top notch search/software platforms like Google, Microsoft and Apple, viz. Google Assistant, Cortana and Siri respectively. Such applications are revolutionizing the information retrieval world by providing users a personalized experience. Whenever users search any new information with these search applications, a personalized search profile is automatically created in these applications which gets more intelligent and search efficient as we go. Anything new appears or gets updated on web that is related to the personalized search profile an alert pops up for users via these applications. These applications, thus, are intelligent personal assistants and knowledge guides that always keep users updated about their interests and help them get desired information retrieved without much efforts.

FUTURE RESEARCH DIRECTIONS

Future of the Web is relying on how intelligent and efficient web retrieval tools will become. The smart web is relying on further development of these wonder tools. Therefore, developing proper

structure linkages and relations between the data is imperative for any search tool. The semantics of data is paramount in the success of any online retrieval tool. So it would be interesting to study the stages of developing this semantics by prominent search tools, and how far they have attained their goals. Besides investigating how far major search tools will allow metadata cross walks for better retrieval efficacy can be an interesting area of future research.

CONCLUSION

With the advent of Gutenberg moving printing press, information began to be produced, reproduced and communicated at large scale and people began to think to devise systems to facilitate easy and efficient discovery of requisite information. The much prominent amongst the earliest systems were indexing cards which provided very few directions to reach to the information sources. However, there has always been unprecedented production of information which encourages, rather compels to devise new and to improve upon existing systems. Information retrieval systems also witnessed machine-controlled indexing systems which were more or less machine equivalent of card system but with brighter scope of easy information retrieval. In the current era dominated by presence of electronic gadgets in every sphere of human activity, information retrieval systems have taken a leap ahead making use of artificial intelligence and semantic web. It would be more exciting to observe what is next to come in the domain of human-machine and machine-machine resource discovery and access. With each new approach, the retrieval relevancy of information retrieval systems is moving towards more balance between its precision and recall. The semantic web and context based personalization are evolving as unique modes to offer precision based information to the user. These two new features if properly synchronized can yield better efficiency and higher level of satisfaction with the information

retrieval system and can enormously help users to avoid retrieving noise to great extent. Besides researchers are also getting very close to evolve a comprehensive multimedia content retrieval mechanism which can retrieve precise part of multimedia file and play the specific portion out of whole. We expect to use these revolution information retrieval systems in near future which can further alleviate the difficulties faced by the end users.

KEY TERMS AND DEFINITIONS

Bibliographic Database: An organized collection of references to the available literature. Some primary examples include MeSH, MEDLINE, Web of Science, Scopus, etc.

Information Retrieval: An activity of tracing information from a collection of information resources and recovering back the relevant results as per needs of information seekers.

Indexing: A mechanism facilitating the retrieval of relevant information with the help of an alphabetical list of keyword terms, subject headings, etc. called as index.

Knowledge Base: A database of information that is collected, manipulated, revalidated and accumulated with the passage of time so as to aid in better informed decision making in future endeavours. Here concepts like artificial intelligence and semantic web are made use to facilitate services like reasoning, explanation, etc.

Ontology: A formal representation of knowledge as a set of concepts within a particular domain and the relations between these concepts.

Semantic Web: An extension of World Wide Web providing standardized way where information systems understand the meaning of hyperlinked information and show relationships between web pages.

World Wide Web: An information space invented by Tim Berners-Lee in 1989 and available through internet where information resources are available and identified by Universal Resource Locators (URL) and linked with each other by hypertext links. The term ‘World Wide Web’ now-a-days is synonymously used simply with ‘Web’.

Adaptive Networks for On-Chip Communication

Mário Pereira Vestias

Instituto Politécnico de Lisboa, Portugal

INTRODUCTION

Networks-on-Chip (NoC) are a scalable inter-connection network for on-chip communication capable to integrate a high number of processing elements. Scalability, energy efficiency and reliability are among the most important advantages of this new communication paradigm. Hundreds or even thousands of cores can be integrated in a single device using a NoC structure without facing the non-scalability problems associated with bus-based structures or point-to-point connections which are usually irregular and harder to route. Global on-chip communication with long wires thus not scales down with increasing clock frequency. The new communication paradigm decouples the cores from the network, reducing the need for global synchronization, reduces the number of global wires and the energy consumption of cores can be individually controlled. NoC are also reliable since fault-tolerant techniques can be implemented from hardware redundancy to adaptive routing protocols that look for alternative paths for a communication.

The first generation of NoC solutions considers regular topologies, typically 2D meshes under the assumption that the wires' layout is well structured in such topologies. Routers and network interfaces between IP cores and routers are mainly homogeneous so that they can be easily scaled up and facilitate modular design. All advantages of a NoC infrastructure were proven with this first generation of NoC solutions.

However, soon, the designers started to be worried about the two main disadvantages associated with NoCs, namely, area and speed overhead.

Routers of a NoC need space for buffers, routing tables, switching circuit and controllers. On the other side, direct bus connection is always faster than pipelined connections through one or more routers since these introduce latency due to packaging, routing, switching and buffering.

In a first attempt to consider area and latency in the design process, designers considered that regular NoC structures may probably be adequate for general-purpose computing where processing and data communication are relatively equally distributed among all processing units and traffic characteristics cannot be predicted at design time. But, many systems developed for a specific class of applications exhibit an intrinsic heterogeneous traffic behavior. Since routers introduce a relative area overhead and increase the average communication latency, considering a homogeneous structure for a specific traffic scenario is definitely a waste of resources, a communication performance degradation and an excessive power consumption.

Application specific systems can benefit from heterogeneous communication infrastructures providing high bandwidth in a localized fashion where it is needed to eliminate bottlenecks (Benini & De Micheli, 2002), with sized communication resources to reduce area utilization, and low latency wherever this is a concern.

Homogeneous and heterogeneous solutions of first generation NoCs follow different design methodologies but have one thing in common: their architectures are found at design time and are kept fixed at runtime, i.e., the topology and the architecture of the routers are fixed at design time. Apparently, this is not a problem, but since

several applications may be running with the same NoC, the same topology and router will generally not be equally efficient in terms of area, performance and power consumption for all different applications. The efficiency of both homogeneous and heterogeneous solutions can be improved if runtime changes are considered. A system running a set of applications can benefit from the runtime reconfiguration of the topology and of the routers to improve performance, area and power consumption considering a particular data communication pattern. Customization of the number of ports, the size of buffers, the switching techniques, the routing algorithms, the switch matrix configuration, etc. should be considered in a reconfigurable NoC. Both general purpose and application-specific System-on-Chips (SoCs) will benefit from using dynamically reconfigurable NoCs since the performance and power consumption of data communication can be optimized for each application.

The second generation of NoCs are dynamic or adaptive providing a new set of benefits in terms of area overhead, performance, power consumption, fault tolerance and quality of service compared to the previous generation where the architecture is decided at design time. To improve resource efficiency and performance, the NoC must consider adaptive processes at several architectural levels, including the routing protocols, the router, the network interface and the network topology.

This article focuses on adaptive Networks-on-Chip. Adaptive topologies and adaptive routers are described in the following sections.

BACKGROUND

More than a hundred of proposals of NoC architectures can be found in the literature (Salminen, Kulmala & Hämäläinen, 2008). These NoC proposals differ in the used topology, the routing and the switching schemes, the design metrics and the target application. Routers have been also extensively studied, designed and implemented

with different flit widths, buffer sizes, switching and routing mechanisms considering latency, area, power consumption, fault-tolerance, quality-of-service, among other metrics. However, only few works have considered adaptive techniques where the NoC can be adapted to the communication requirements statically or at runtime.

Deterministic routing always uses the same route for a particular destination without considering any information about the state of the network. Adaptive routing considers the state of the network, such as the status of a link or buffer, to route data, to route data across the network. Compared to adaptive, deterministic routing requires fewer resources while guaranteeing an ordered packet arrival. On the other hand, adaptive routing provides better throughput and lower latency by allowing alternate paths. Deterministic routing is more appropriate if the traffic generated by the application is predictable, while adaptive deals better with irregular networks and/or stochastic traffic. Deterministic routing usually has poor capacity to equally distribute the traffic along all links of the network since the routes are statically assigned independently of the traffic requirements. On the other hand, highly adaptive algorithms have the potential to reach a uniform utilization of resources and provide fault tolerance. These algorithms distribute the traffic through all links to reduce congestion. However, the efficiency of highly adaptive algorithms is compromised by the necessity to guarantee deadlock free scenarios. Generally, having these algorithms adaptable requires a number of virtual channels (Bjerregaard & Mahadevan, 2006) increasing the cost of the solution compared to that using deterministic routing. Several adaptive routing methods were proposed, as described in the next section.

The proposed adaptive routing algorithms run under the same topology and router configurations, and thus the optimization that can be gained with the adaptive routing is limited by the structure of the NoC and their network components. Besides, highly adaptive routing algorithms are expensive in terms of virtual channels and, consequently,

increase the area overhead. Reducing the number of virtual channels usually means that the adaptiveness of the algorithms and hence the efficiency of the approach are reduced. Adaptable communication structures can be implemented with reconfigurable technology. Given a particular application or traffic behavior, it is possible to dynamically change the topology according to the interconnection requirements. The basic idea would consist on keeping the number and size of resources and then dynamically change the way the routers are interconnected to form the network topology.

The topology of the network and the routing mechanism to be followed are two important design optimizations to be considered in the development of a NoC. However, router optimizations are also fundamental to reduce area overhead and latency. Several aspects may be considered in the optimization process of the router: number and size of buffers, switch matrix structure and number and size of links. The optimization of the switch matrix is also very important since for specific technologies (e.g., FPGA – Field Programmable Gate Array) this is one of the most area consuming resource. Buffers also take a significant portion of the area and power consumption of a NoC (De Michelli & Benini, 2006) and so their size must be carefully minimized. Reducing the size of buffers has a negative impact over the performance of the NoC, especially when the network becomes congested. However, recent works (Martini et al., 2007; Medardoni et al., 2007) show that as the switch buffer size is decreased, the clock frequency can be increased.

Runtime switching is another technique that tries to improve the NoC by changing the switching protocol. For example, circuit switching is more appropriate to guarantee quality of service, while packet switching is more efficient for best effort traffic. Therefore, it is natural that according to the traffic type, the router dynamically changes the switching type.

According to above state-of-the-art, second generation NoCs are still in its infancy. Basic run-

time topology configuration and dynamic switching together with adaptive routing algorithms were the first attempts towards a dynamically reconfigurable NoC. Runtime router configuration with an adaptive structure is still an open issue that must be mitigated so that an integrated runtime NoC will be designed.

ADAPTIVE NETWORK-ON-CHIPS

A network-on-chip is enough to support the communication of a wide range of different applications in a single hardware platform. The NoC supports different bandwidth and quality-of-service requirements. Generically, the flexibility is achieved employing an over-engineering bandwidth capacity. The problems associated are that the NoC interconnection network takes a significant number of resources and it is in general under-utilized by a given application. Adaptive networks-on-chip try to statically or dynamically redistribute the resources and available bandwidth following the traffic requirements of each specific application. This will permit to reduce the required resources and consequently the area and power consumption of a NoC.

In the following, several adaptive techniques are analyzed including adaptive topologies and adaptive routers.

ADAPTIVE TOPOLOGIES

A few state-of-the-art proposals of dynamically reconfigurable NoCs have focused their attention into the reconfigurable topology. Stensgaard & Sparsø (2008) present a NoC architecture with a reconfigurable topology. The logical topology is configured at design time based on the communication requirements of the application. Topology switches are introduced between the network and the routers allowing links to be connected to a port of a router or to another link, whether using packet switching or circuit switching, respectively.

In the CuNoC approach (Jovanvic et al., 2007) the reconfigurable device approach is filled with small units that can establish a communication between two cores. This approach suffers from huge power consumptions and high latency due to the significant number of units in a communication path. CoNoChi (Pionteck, Koch & Albrecht, 2006) is an adaptable NoC. The reconfigurable device is divided in a matrix where each cell can hold a computational module, and a switch or a point-to-point link. This approach has major drawbacks, including high area overhead and latency. Ahmad, Erdogan & Khawam (2006) present a dynamically reconfigurable NoC, where routing, switching and data packet size can be dynamically reconfigured, but resources are fixed at design time. Kumar et al. (Kumar et al., 2007) follow a similar approach where runtime configuration reduces to a simple change of the contents of a memory. Topology, buffers and port connections are determined at design time. In (Rana et al., 2008), a runtime reconfigurable NoC is presented using an FPGA. The NoC can add or remove express lines, and perform run-time NoC topology and routing table reconfiguration to deal with traffic congestion.

Topology customization at runtime is achieved at the cost of extra area overhead and latency increase. In fact, the topology is somehow optimized for a specific runtime application permitting to use the available bandwidth more efficiently but if we consider the occupied resources the efficiency of the solution typically decreases. Reconfigurable properties of FPGA technology are used to implement adaptable topologies but still suffer from high delays to reconfigure the interconnection topology.

ADAPTIVE ROUTERS

The structure and the behavior of an adaptive router can be statically or dynamically reorganized given the quests for specific traffic bandwidth requirements. For example, a router may decide at runtime to use a second parallel link or

increase the buffer size to a specific direction. Using an adaptable structure for the router will provide better performance since its architecture adapts to the traffic requirements to achieve the best possible performance. An adaptive router tries to achieve the same performance of a static router using fewer resources and better switching and routing decisions. Reducing the number of resources (e.g., buffers, links, etc.) for packet routing is compensated by the flexibility to redirect the resources and efforts of the router to where it is most needed. Several customizations can be considered for an adaptive router (e.g., routing, switching, buffers). Runtime adaptive routers were considered in (Véstias, M. & Neto, H., 2010) where several adaptive techniques are proposed to dynamically customize a router to network traffic.

Adaptive Routing

Adaptive routing algorithms can be used to dynamically change the routes given the traffic requirements and the links' congestion. The approach is very attractive from the point of view of the compiler since the routing process is managed by the network controller. The disadvantage compared to static routing is that it needs a well-designed protocol to maintain information about the utilization of the links for the router to take good routing decisions.

An alternative is to determine the routes of each application at compile time and then change the routing tables before starting the execution of each particular application. This option is attractive for the network since it just has to support the reload of new routes, while it is harder for the compiler that must determine the best routes for each application. Compared to the approach using adaptive routing algorithms this is easier to achieve and possibly will offer better performances, but only applies to applications whose traffic pattern is known at compile time. On the other side, adaptive routing algorithms have a much broader usage since they can be used in all types of applications, whether specific or generic.

Soon, researchers have started to improve the performance of routing algorithms using adaptive techniques (Duato, 1993; Chiu, 2000). Solutions exist that base their routing decisions on the load state of the buffers of neighbor routers (Ascia, et al., 2006), (Dong et al., 2006). Another one dynamically determines its routes using the distance to destination and current link bandwidth utilization (Faruque, Ebi, Henkel, 2007). Others Hu & Marculescu (2004) have proposed a smart routing for networks-on-chip which is a combination of static and dynamic routing. The router switches between Odd-Even and XY routing using a simple congestion monitoring. XY routing was also improved to load balance the traffic (Dehyadgari et al., 2005). Pseudo adaptive XY-routing uses the deterministic XY-routing algorithm under low congestion and adaptive routing under heavy traffic conditions. A fully adaptive algorithm was proposed in (Bartic et al., 2005) using an operating system to program the routing tables. Li et al. (Li, Zeng, & Jone, 2006) proposed a dynamic XY (DyXY) fully adaptive routing scheme. Virtual channels are used to guarantee deadlock avoidance. The EDXY adaptive algorithm was proposed in (Lotfi-Kamran, P., et al., 2010) as an enhancement of the DyXY algorithm that includes a congestion-aware mechanism. In (Chang, E.-J., et al., 2015) an adaptive routing scheme is proposed that simplifies the implementation of an adaptive routing algorithm based on ant colony optimization (Hsin, H.-K. et al., 2015). In (Kumar, M. et al., 2014) an adaptive and deadlock free routing algorithm for a 2D mesh topology is presented. The algorithm uses all available minimal/non-minimal paths between source and destination nodes. A packet is routed along the non-minimal path when minimal paths get congested at the neighboring nodes.

Deterministic routing algorithms is usually the best choice for uniform or regular traffic patterns, while adaptive routing is preferable to forward non-uniform or bursty traffic or in the presence of unreliable links. Another disadvantage of adaptive routing is that packets may arrive to the

destination from different paths and with different latencies and packets may arrive out of order, requiring dedicated resources, including memory, for packet ordering.

Adaptive Switching

Switching can be dynamically changed between wormhole or virtual cut through and circuit switching to guarantee the requirements of some delay sensitive traffic. Runtime switching was considered by Wang et al. (Wang, Gu & Wang, 2007) that proposed a hybrid switch mechanism to guarantee quality of service for real-time applications. In this approach, circuit switching is used for real-time traffic and virtual cut through switching is used for best effort traffic. At runtime, data is identified according to the type of switching to be used for their commutation within each router.

The decision about the type of traffic is taken at the source of the data, i.e., the processing unit. Then, the network interface adds one bit to the header of the packet to indicate the type of traffic. When the router receives the packet it checks the type of traffic. In the case of best effort traffic, the packet is sent to the appropriate output using wormhole or virtual cut through switching. Otherwise, the router initiates a process to reserve an output port for circuit switching, namely: (1) requests a dedicated link, (2) the associated output arbiter grants the link as soon as the link is free and (3) the input releases the link at the end of the message. All the routers belonging to the path from the source to the destination processing units (circuit) do the same port reservation. The circuit is kept reserved until the end of the transmission of the message or set of messages associated with a specific flow.

Adaptive switching is usually used to support concurrent communication of best-effort traffic and real-time traffic. Circuit switching is used for real-time traffic, while wormhole or virtual cut through switching is used for other types of traffic.

Adaptive Buffering

In general, buffers are not equally utilized. Therefore, some are under-utilized while others are overutilized. Adaptive routing can alleviate somehow this unbalanced utilization but in some cases we could consider adaptive buffer resize.

Adaptive buffer resize have also been proposed for NoC adaptability. In (Al Faruque, Ebi, Henkel, 2008), the architecture uses a runtime agent to observe the presence of faults and remap tasks, reroute packets or reallocate buffers. In (Concatto, C., et al., 2009) a router can resize a buffer at run-time by moving slots buffers from one port to another. In (Matos, D., et al., 2009) buffer adaptation is based on a flow sensor that watches the traffic at run time, then a control equation adapts itself to change the buffer size of each port to achieve better performance. In (Soteriu, V., et al., 2009), the authors use a shared buffer scheme to improve the input-buffering technique. The solution statically groups pairs of inputs to each of the two buffers. In (Wang, L., 2009), a centralized buffer structure is proposed, which dynamically allocates buffer resources using linked lists. In (Véstias, M., 2011), a dynamic buffer resize technique was proposed for FPGA.

Buffer resizing is an expensive process in terms of resources. So, in general its applicability is very limited. Static resize of buffers achieves very good and efficient results but less efficient results are obtained with adaptive buffer resize due to the complexity associated with the hardware circuitry needed to dynamically resize of buffers.

FUTURE RESEARCH DIRECTIONS

There are a number of dynamic customizations that can be utilized in the design of NoC, including adaptive topologies, adaptive routing, adaptive switching, adaptive buffer resize and also adaptive network interfaces (Diguet, J.-P. 2014). Each technique achieves different tradeoffs between performance, area and power consumption.

Also, the methods are correlated, that is, using one method reduces the effectiveness of another and so the appropriate combination of techniques must be subjected to a careful analysis in order to optimize the final network-on-chip solution. The adaptability of the NoC increases the size of the design space. So, the development of efficient design methodologies and tools to help the designer explore such huge space is therefore a very important topic of research. One possible approach is to iteratively apply the customization techniques starting with those considered more efficient to improve the performance or the area.

A major open problem in the design of adaptive Networks-on-Chip is which set of adaptive techniques should be used for a specific architecture to obtain the most efficient solution in terms of area, performance, power consumption and/or other requirements. In a lower level of the design process, more efficient adaptive solutions are required either taking advantage of the technology (e.g. reconfigurability of FPGA technology) or considering new architectural structures with efficient adaptability. Considering the number of works produced within this subject, it seems that adaptive routing is the easiest the apply to a NoC. It does not mean that it is the most efficient solution. Topology optimization is in general a very efficient approach but unless it is applied statically, dynamically changing the topology is a complex process that requires some reconfigurability or adaptability of the hardware.

All adaptive customization methods rely on timely information about the congestion of the network. Typically, adaptive methods rely on neighbor information about the state of buffers and the utilization of links. While this is a simple solution it is important to research other data gathering methods relying on information beyond local information; what can be achieved in terms of performance, area and power consumption considering the costs associated with the data gathering system.

Static versus dynamic adaptation must be considered in all adaptation techniques. Static

adaptation requires knowing traffic patterns at compile time but reduces the complexity of the NoC as well as the process of gathering and analyzing traffic data at runtime. On the other side, dynamically adaptable NoCs requires dynamic traffic analysis. Static adaptation is probably most appropriate for data oriented applications, while the dynamic method is for control oriented. Which one is most appropriate for a determined application should also be explored. An hybrid static-dynamic solution should also be investigated, where some adaptable parts of the NoC are static while others are dynamic.

Many applications have real-time tasks with real-time traffic associated. Several works have proposed techniques to deal with such real-time requirements, namely: reservation of virtual channels, prioritization of traffic and circuit switching for real-time traffic. Additional aspects must be considered in the design of adaptive NoC for real-time applications: the influence of the discussed adaptation methods and how they can be used in the design of routers with support for real-time traffic.

Power consumption is an important aspect of many on-chip systems. Several works have analyzed the power consumption of NoC and how to reduce the power consumption. Similar analysis must be considered for adaptive NoC to see how the adaptation techniques affect power consumption.

Recent many-core architectures with hundreds or more cores are a challenge for adaptable NoC architectures. In these cases, hierarchical interconnection structures with different communication topologies, including buses, crossbars and point-to-point links, are a promise of better communications than just using a single NoC. These cases, require adaptable NoCs to be designed for hierarchical heterogeneous interconnection structures where adaptability may be applied at all levels or NoC may have to be reconfigurable to model different communication structures.

CONCLUSION

The article describes the backgrounds of adaptive Networks-on-Chip. Different ways and aspects of adaptability are explained and state-of-the-art implementations are referenced.

A considerable number of publications, patents and implementations have appeared during the last 50 years about adaptive interconnection networks. However, there is still work to be done on the design of adaptive NoC, to find how different techniques achieve different results, how do they influence each other and how far can we go with these adaptive techniques. Adaptive topology at low cost is an open research problem less researched when compared to adaptive routing techniques. However, adapting the topology seems to be very efficient to improve communication delay and latency. So, the research about adaptive NoC is an actual topic of research.

KEY TERMS AND DEFINITIONS

Adaptive Buffering: Refers to a technique that can change static or dynamically the structure or the behavior of buffers inside a router of a network-on-chip given the traffic requirements and the links’ congestion.

Adaptive Network-On-Chip: A network-on-chip with some form of adaptability to the traffic patterns. The adaptation of the network-on-chip can be static if it is done at design time or dynamic if it is done at runtime.

Adaptive Routers: Refers to network-on-chip routers that static or dynamically adapt themselves to the traffic requirements.

Adaptive Routing: Refers to routing algorithms that can change the routes static or dynamically given the traffic requirements and the links’ congestion.

Adaptive Switching: Refers to switching algorithms that can change static or dynamically the switching method inside a router given the traffic requirements and the links' congestion.

Adaptive Topology: A network-on-chip topology whose structure and connections can be

changed static or dynamically according to the traffic requirements.

Network-On-Chip: A new communication paradigm consisting of a scalable interconnection network for on-chip communication capable to integrate a high number of processing elements.

Business Model Innovation– Oriented Technology Management for Emergent Technologies

Sven Seidenstricker

Fraunhofer Institute for Industrial Engineering, Germany

Ardilio Antonino

Fraunhofer Institute for Industrial Engineering, Germany

THE CHALLENGE IN TECHNOLOGY MANAGEMENT

During past decades the requirements of research institutions and technology-oriented companies has changed radically. Competition for customers and markets, as well as within research and development, is carried out at global level. Furthermore, the high speed dynamics of technology markets lead to constantly shorter product and technology life cycles.

Traditionally, technology transfer into the market was conducted by cost-cutting and/or innovation. However, in many cases research institutions as well as companies concentrated mainly on the improvement of their current value proposition (technology and/or product). Potential in providing new services and organisational innovations as well as innovations within the business model often remained unused. However, sticking rigidly to traditional business methods is often no longer possible and can lead to the viability and survivability of institutions or companies being endangered. In particular, research institutions in the area of applied research face this problem, as their mission is to transfer technologies into the market.

Therefore, it will be increasingly significant for research institutions and technology-oriented companies to pursue developments and trends

in industries such as markets, customer groups, technology fields, etc. and to identify growth areas and applications outside their current market and field of application. Thus, R&D effort can be reached sooner. Different applications often require several concepts of technology commercialisation. The concept can differ in terms of the number of essential partners, the value chain, the kind of value proposition, the kind of revenue achievement, etc. Technology exploitation claims a holistic consideration of all relevant issues in terms of developing new business models for the emergent technology (Nair & Paulose, 2014; Boons et al., 2013).

Unfortunately, the majority of research institutions, as well as technology-oriented companies, do not deal enough with these challenges (Bezerra, Barquet et al., 2013). Often they are not sensitised to, or are rather scared of, the laborious process behind the identification of new markets and professional technology commercialisation. The purpose of this paper is to describe some crucial steps to improve the outcome of technology management, in particular professional technology commercialisation to support institutions of applied research and technology-oriented companies and to detect white-spots in the technology and research landscape from a market perspective to increase efficiency and effectiveness in the development of emergent technologies.

OBJECTIVES OF BUSINESS MODEL INNOVATION-ORIENTED TECHNOLOGY MANAGEMENT

The diffusion of new technologies into the market, even if they have a large potential, is difficult. Many technologies require a period of years before they are adopted by the social system. In some cases, technologies never make it into the market (Baden-Fuller & Haefliger, 2013; Gómez & Vargas, 2012).

The diffusion of emergent technologies into the market needs to aim at increasing the diffusion rate (quantity) and decreasing the adoption time. The diffusion rate is the relative speed at which an innovation is adopted by members of a social system (Rotolo, Hicks & Martin, 2015; Planing, 2014; Rogers, 2003). A good technology diffusion rate implies a bigger market demand and, therefore, greater potential for the company or institution in terms of marketing their technology. Decreasing the adoption time brings advantages in terms of competition as competitors need to develop their technologies and/or adopt their business models in order to address the same market. However, if the gradient is too high, companies and/or institutions can face problems with the provision of the technology to the customer. In this case, the demand is much higher than existing resources

can handle. The big challenge for research institutions and companies is to achieve these objectives successfully. Smart Home Technologies or Green Technologies are examples of how commercialisation has had a huge impact on the success of technology as a whole (Karakaya, Nuur, & Hidalgo, 2016; Bohnsack, Pinkse & Kolk, 2014).

Technology commercialisation and detecting markets at an early stage of technology development has been considered in the research on technology management and for the last 10 years. At the same time, another research topic, called business model innovations, was becoming more and more important. Some leading researchers into innovations announced the idea that business model innovations were more significant than technology innovations. However, some of the business model innovations wouldn't exist without the possibilities of new technology. Nevertheless, business model innovations can boost emergent technologies, so this approach should be used to increase the diffusion rate and enhance the competitive strength of a new technology from the beginning (Figure 1). Business models should offer advantages along the value chain (not only for the end user, but also for all other stakeholders) and dissolve industry structures and market barriers (which could result in competitive advantages). Through new business models, the rate of

Figure 1. Boosting emergent technologies through business model innovations

technology-diffusion of research institutions and technology-oriented companies can be increased by addressing new markets and/or improving within established markets.

HOW TO ACHIEVE THE AFOREMENTIONED OBJECTIVES?

Developing innovative business models does not exactly follow the guidelines described nor can it be predicted, but some crucial steps can be recognised in order to enhance the probability of creating a successful business model. The first step is a systematic identification of potential markets. Within these identified markets the analysis of existing business models should be the second step. Based on these two steps new attractive and competitive business models should be developed. The development of different ideas and approaches which challenge the established market leader and existing business models represents the third step. The idea development and the assessment of different ideas in the early stage of technology development allows for an influence on the research and development activities of the new technology and can be used to derive certain crucial technical requirements and adapt the technology development roadmap positively. All three steps support the increase of the diffusion rate, the decrease of the adoption time and the optimisation of the competitive advantage; these steps are shown in Figure 2.

Figure 2. Steps to develop new business models for emergent technologies

Identification of Relevant Markets

In order to be able to discover relevant markets for technologies, the current and potential applications for such technologies have to be identified. Current applications in this context means applications which are already distributed in the market for the technology under consideration, while potential applications are either addressed by a competitive technology or do not yet exist in the market.

The identification of applications for a technology is either orientated towards methods for idea generation or can be supported by intelligent patent research. In both cases, the functional profile of the technology plays a major role. The functional profile for the technology covers the whole set of functions and its performance parameters. This profile will be mapped to different branches through patent searches or a creativity session based on branch lists (like NACE-Code etc.). If the accepted function of a technology appears in patents, the associated IPC-Code gives a hint of the application field.

From the discovered applications, those which could already be addressed by the technology, and for which, therefore, no further development of the technology was needed, were dismissed from further consideration. Applications whose technological implementation was highly unlikely within the time-period under consideration were also excluded from further consideration. Outputs from this phase are made up of attractive potential applications for the technology. However, some of these markets cannot be addressed immediately by the technology due to performance or cost.

Analysing the Existing Business Models Within the Identified Markets

The determination of existing business models requires a concept that can describe and analyse 'real' business activities. There are many different business model concepts available in business model research; however, despite their differences,

which are illustrated by many papers, there is widespread recognition that business models have to be understood as the connection of many different business elements and that business models can be described and designed by using those elements.

However, there is disagreement regarding what the fundamental business elements are and how they characterise a business model. Shafer, Smith and Linder (2005) and Onetti et al. (2012) sought to compare different approaches in terms of business models and their elements to find an answer to this question. In consideration of these studies and additional concepts, which were published within the last three years, there are six essential business model elements, namely (Seidenstricker & Linder, 2014):

- Value proposition: this business model element includes all components which create value for the stakeholders of a business model. The value that a business model creates has to be formulated as precisely as possible.
 - Competencies and key resources: this includes the competencies and key resources of a company. These are all key-assets of a business model to capture value for customers and establish unique selling points on one's own behalf.
 - Channels and customer relations: the transmission of the value proposition into an offer and the distribution of this offer to the customer are the realisation of 'channels and customer relations'. The purpose of this is to support the development of customer relations.
 - Value chain and processes: on the one hand, this business model element considers the value chain of the business model referring to the industries and, on the other, the essential processes needed to accomplish the value proposition to the customer.

- Network and partners: this describes and defines the relationships to suppliers, R&D partners and other service providers needed for the business model. The customers could also be partners, particularly when they represent Lead-Users.
- Revenues: the configuration of the financial returns for services around the offer is included in 'revenues'. This element forms the economic basis for the business model.

These six business model elements will be used to establish a business model framework structured by a system theoretical approach. This implies that the business model elements can also be split into different sub elements or options. This technique will be used in the next step which provides different design options for several business model elements (Figure 3).

Identifying Gaps and Leverages to Create Business Model Innovations

The identification of potential markets and the analysis of existing business models should be provided for the business model idea development process, so that they can be used to detect some gaps in the existing business models and derive approaches for business model innovations. The goal in each idea creation process is to develop a huge number of different ideas without any boundaries and limitations. The complexity in the development of new business models needs to be reduced so that idea development has to be carried out for each business model element separately. Each business model element can also be split into different design options and parameter. To merge all the parts into a coherent business model, the combinations in the business models have to be verified and adjusted finely, so that bottom-up and top-down processing are applied (Figure 3).

Analog to this proceeding and to supporting the idea development as much as possible on the

Figure 3. Business Model Framework

level of sub-elements and parameters, different generic design options and parameters should be provided for each business model element. For instance, in the business model element 'revenues' five design parameters can be named each of which can contain different design options. The design options should be described generically and reflect the whole range and typical design possibilities. In the case of the business model element 'revenues', the 'kind of revenue achievement' and 'calculation base' referenced directly to the revenue achievement, and the others, covers the area of the pricing system. In all business model elements such a matrix should be established with parameter and design options. This procedure was derived from morphological

analysis, which structures the problem and splits it into its influencing variables.

After the development of different ideas in each business model element the 'sub-ideas' should be combined and merged to form consistent business model ideas. The development of business model ideas can be realised by 'mentally' combining the individual sub-ideas, similarly to the morphological analysis. The starting point for developing a business model concept logically can be any business model element. It is even advisable to vary the starting point for solution development. Furthermore, when developing solution paths, there is an additional need for other sub-ideas to become visible or more sub-ideas to be generated. If necessary, the matrices with the design

Figure 4. Design options in business model element 'revenues'

kind of revenue achievement	direct revenue achievement	indirect revenue achievement	direct and indirect revenue achievement	
calculation base	result	level	period	usage
approach of pricing	demand-oriented	cost-oriented	competitive-oriented	
price mechanism	fixed one-sided	fixed double-sided	not fixed	
price bundling	non		mixed	

areas and generic design parameters need to be considered again at this point. Further sub-ideas detected have to be added to the table. The aim of this iterative approach is to close possible gaps and to identify new sub-ideas and business model ideas, respectively.

To prioritise the developed business model ideas, all ideas can be evaluated by their potential to change the market, their competitive strength and the effort required for their implementation. A roadmap can enable the timeline to be visualized and show interdependences between business model ideas, R&D outcomes and technology requirements. By using the roadmap, R&D gaps or white-spots in the technology development can be identified, and especially for research institutes this information can be useful in adapting their technology development strategy, focusing their resources and gaining a competitive advantage in comparison to other research institutes.

FUTURE RESEARCH DIRECTIONS

Future work should continue the application of the developed approach to extend the depth and range of business model-oriented technology management. Especially in analysis of existing business models, more research is needed into which technologies are used and which would be of great assistance for research institutions in the commercialisation of their technologies.

In the idea development process, in particular during the creative phase, it might be useful to make use of some more tools, so that more radical ideas can be created. In particular, this might allow for the discovery of potential from digitalisation and how connecting different information sources can support development to create disruptive business model innovations.

The road mapping approach and the tracking of developed ideas and of other conducted studies will help feedback on the effectiveness of such proceedings to be gathered. A dynamic consideration of technology development proj-

ects to generate new business model innovations should also be the subject of further research. As a result, a set of methods within the framework of Business Model Engineering could be created to support companies and research institutions to successfully advance their technologies (at different development stages) into the market.

CONCLUSION

The concept of business model innovation is becoming significantly more important in research and practice and could also advance in technology management for emergent technologies. In terms of the commercialisation of technologies in particular, the business model concept enables a performing, holistic and efficient transfer of technologies into the market. This enables companies and research institutions to identify future potential fields of application for the technology and to secure the feedback of market information relevant to its development.

Hence, especially for emerging technologies where markets are not yet clear, essential 'vital levers' can be identified and directive recommendations concerning future developments can be given. This improves the diffusion of the technology into the market and technology competitiveness.

The business model framework allows the complexity of business models to be broken down in practice and should support the identification of leverage points for business model innovations. After such a breakdown, it is as important that all ideas and leverages are merged into consistent business models. Supporting the creative process and reducing barriers to creative thinking should also be considered during this process. Morphological boxes with design parameter and options are a useful tool to increase the quantity and quality of possible business model ideas. The three aforementioned steps cannot be completed in an exactly predefined sequence; often an iterative process is required. Nevertheless, an in-depth analysis at

the beginning is the first milestone to success in developing new disruptive business models.

Prioritising might also be an important step when focusing on important technology developments; in particular, for technology-driven small and medium-sized companies it is essential that limited resources are used with care to increase outcomes. Tracking and adapting ideas and concepts as well as the progress of implementation and feedback from the market are quite important. Roadmapping and Project Management Tools could be helpful to stay on track and push towards a realisation of the developed business model concepts.

This paper is focused mainly on the generation and evaluation of new business model ideas for emergent technologies. However, it is just the first step – but nevertheless an important component – in advancing the diffusion of a technology and maximising the scope of its competitive strength from the beginning. It should be helpful for scientists and engineers involved in technology development to keep these three steps in mind and to aim to benefit the whole organisation or company.

KEY TERMS AND DEFINITIONS

Business Model: Business model describes the logic of the value generation for customers, stakeholders and the company or research institution.

Business Model Innovation: Business model innovation is a new way to generate value for customers and stakeholders and enables the establishment of competitive advantage for the company or research institution.

Business Model-Oriented Technology Management: Business model-oriented technology management integrates the concept of business model innovation, which means identifying, developing and analysing business concepts, in the management of technologies and technology knowledge.

Diffusion: Diffusion describes the accumulated level of a technology in the market.

Diffusion Rate: Diffusion rate refers to the current quantitative scope of a technology's diffusion.

Emergent Technology: Emergent technology is new and coming to the fore.

Technology: Technology uses physical principles and scientific laws to realise technical functions.

Technology Management: Technology management covers all aspects of organising technology knowledge, technology forecasting, technology development, technology commercialisation and technology usage through the technology life-cycle.

Cognitive Mapping in Support of Intelligent Information Systems

Akbar Esfahanipour

Amirkabir University of Technology, Iran

Ali Reza Montazemi

McMaster University, Canada

INTRODUCTION

Cognitive mapping techniques consist of a set of procedures to capture perceived relationships of attributes related to ill-structured decision problems that decision makers have to face. This paper provides an overview of the application of cognitive maps (CMs) in the design and development of intelligent information systems. Here, CM is used as a set of techniques to identify subjective beliefs and to portray those beliefs and their relationships externally as follows:

- Causal mapping is used to investigate the cognition of decision-makers. A causal map represents a set of causal relationships (i.e., cause and effect relationships) among constructs within a system. For example, Figure 1 shows that better sanitation facilities, causing an initial improvement in health, led to an increase in the city's population. This growth led to more garbage, more bacterial, and therefore more disease. Causal map aids: 1) in identification of irrelevant data, 2) to evaluate the factors that affect a given class of decisions, and 3) enhances the overall understanding of a decision maker's environment, particularly when it is ill-structured.
- Semantic mapping, also known as *idea mapping*, is used to explore an idea without the constraints of a superimposed structure. A semantic map visually organizes related

concepts around a main concept with tree-like branches. Figure 2 depicts different types of transportation, organized in three categories: land, water, and air. This technique facilitates communication between end-users and system analysts in support of information requirements analysis.

- Concept mapping is a useful tool for organizing and representing concepts (events or objects) and their interrelationships in a particular domain. Each concept is designated with a label. The relationship between two concepts in a concept map is referred to as a proposition; propositions connect concepts to form a meaningful statement. Relationships between concepts are associative. For example, in Figure 3, two concepts of "plants" and "flowers" are associated via "may have" that form the proposition of "plants may have flowers." Describing complex structures with simple propositions improve quality of conceptual modeling in the development of information systems.

BACKGROUND

Cognitive Map (CM) has been employed to capture, store and retrieve expert knowledge in support of the design and development of intelligent information systems. CM is a representation of the relationships that are perceived to exist among the elements of a given environment. Taking any

Figure 1. Causal map for public health issues

two of these elements, the concern is whether the state or movement of the one is perceived to have an influence on the state or movement of the other (both static and dynamic relationships can be considered) (Montazemi & Conrath, 1986). CMs have been used to describe experts' tacit knowledge about a certain problem, particularly in ill-structured decision problems (Axelrod, 1976; Montazemi & Chan, 1990; Amer et al. 2015). Tacit knowledge is personal knowledge, shared

and exchanged through direct and face-to-face contact among actors (Eden, 1988).

There are different perspectives of knowledge within organizations (Nonaka, 1994). Thus, it seems appropriate to use knowledge management categories to identify different applications of cognitive map in the design and development of intelligent information systems. Alavi and Leidner (2001) provide a framework that is grounded in the sociology of knowledge and is based on the

Figure 2. Semantic map for different types of transportation

Figure 3. Concept map for plants

view of organizations as social collectives and “knowledge systems.” They contend that organizations as knowledge systems consist of four sets of socially enacted “knowledge processes” as follows:

- **Knowledge Application:** Those activities concerned with deploying knowledge in order to produce goods and services. Information technology can enhance knowledge application by facilitating capture, updating and accessibility of organizational directives.
- **Knowledge Storage/Retrieval:** This is also referred to as *organizational memory*, which includes knowledge residing in various component forms, including written documentation, structured information stored in electronic databases, codified human knowledge stored in expert systems, and tacit knowledge acquired by individuals.
- **Knowledge Transfer:** Transfer of knowledge to locations where it is needed and can be used. This can occur at various levels: transfer of knowledge between individuals, from individuals to explicit sources, from individuals to groups, between

groups, across groups, and from groups to the organization.

- **Knowledge Creation:** Developing new content or replacing existing content within the organization’s tacit and explicit knowledge. Through social and collaborative processes as well as through the cognitive processes of the individual, knowledge is created, shared, amplified, enlarged and justified in organizational settings.

A literature search shows that application of CMs in intelligent information systems can be found in support of the above four categories of knowledge processes, as depicted in the Appendix, Table 1. A brief description of each of the above four categories within the context of CMs is presented next.

KNOWLEDGE PROCESS THROUGH CMs

Knowledge Application

Cognitive mapping techniques (e.g., causal mapping, semantic mapping and concept mapping) have been used to improve the processes of the

design and development of information systems. They include improvement of conceptual modeling (Siau & Tan, 2005a), user–database interaction (Siau & Tan, 2006) and applicability of the resulting information systems (Siau & Tan, 2005b). Siau and Tan (2006) proposed a framework of user–database interaction in support of knowledge application. According to this framework, user–database interaction has three dimensions -- content, structure and style. The content (i.e. semantics) dimension is determined by the user's data needs. The structure dimension is determined by both the user's perceived data model (constituent structure) and by the query language (syntactic structure). The style dimension is dictated by user–database interface.

CM techniques have been applied in diverse areas for knowledge processing. For example, Papageorgiou et al. (2012) formalized medical knowledge using Fuzzy Cognitive Map (FCM) and semantic web approach in support of therapy decision making in medicine treatment. Here, FCMs are applied for the case of modeling and knowledge integration of clinical practice guidelines in the form of if-then fuzzy rules, and used the semantic web tools to implement the FCMs. Their semantic web approach, to formalize the FCMs, is based on two notions: 1) to develop a common model of integration and use of data from disparate sources; and 2) to link data with real world objects, for machines and humans to access data on different bases related by semantic relations. FCM techniques have also been used to develop diagnosis decision support systems based on clinical guidelines in the form of case-based FCMs (Douali et al., 2015). In another application of FCMs, Amer et al. (2015) develop a national-level wind energy roadmap through scenario planning in which multiple future scenarios are developed using FCMs. Also, Kim et al. (2016) suggest a FCM-based approach for scenario building from expert opinions.

CM techniques can also help decision makers in design of risk management strategies. For example, risk managers are interested in

incorporating stakeholder beliefs into their risk assessment planning process. Techniques for diagramming stakeholder mental models enable risk managers to better understand stakeholder beliefs and perceptions concerning risk in support of their risk management strategies. These risk management (RM) techniques can be categorized as: decision-analysis-based mental modeling, concept mapping, and semantic web analysis (Wood et al., 2012). For example, Van Winsen et al. (2013) propose a CM technique, combining the three types of RM techniques, to identify and represent risk perception faced by farmers. Lopez & Salmeron (2014) develop an FCM, i.e., the first RM technique, in support of ERP maintenance risk management. They modeled ERP maintenance project outcomes and risks perceptions. Aju Kumar et al. (2015) propose an FCM technique to assess human reliability in plant maintenance environment.

Knowledge Storage/Retrieval

Cognitive mapping techniques have been also applied to acquire a decision maker's tacit knowledge when faced with ill-structured decision problems such as the extraction of expert knowledge to forecast stock prices (Montazemi & Chan, 1990), the building of expert systems to control electronic data interchange (Lee & Lee, 2007), for negotiation in a B2B system (Lee & Kwon, 2006) and for analysis of firms with regard to their creditworthiness (Noh et al., 2000). CMs have been used to develop a specific method to analyze complex problems. For example, Satur and Liu (1999) developed an inference method in support of geographic information systems and Kwon et al. (2002) proposed a structural analysis method for a DSS in support of urban planning. Noh et al. (2000) adopted CMs to formalize tacit knowledge and proposed case-based reasoning as a tool for storage/retrieval of CM-driven tacit knowledge in the form of frame-typed cases. Lee et al. (2013) applied fuzzy cognitive maps (FCM) to industrial marketing planning. They proposed

an agent based inference method to overcome dynamic relationships, time lags, and reusability issues of FCM evaluation.

Lu et al. (2014) proposed a modeling and prediction approach of time series based on synergy of high-order fuzzy cognitive map and fuzzy c-means clustering. They contend that this approach ameliorate the prediction problem of large-scale time series. This is extraction of explicit knowledge from historical time series data that can be stored/retrieved in the form of CMs.

Knowledge Transfer

Cognitive maps have been applied in group decision making for the exchange of ideas and opinions between group members in regard to a specific problem. For instance, Caliskan (2006) used the CM technique to facilitate the evaluation of transport investment alternatives using a group of experts. Sengupta and Te'eni (1993) studied the impact of cognitive feedback on group decision making at three levels: individual, interpersonal and collective. They contend that for the development of a group decision support system (GDSS), cognitive feedback should be considered as an integral part at every level, and that a human-computer interaction should be designed as an effective transition across the components of feedback at all levels. Khan and Quaddus (2004) present a methodology for the development and analysis of FCM as a GDSS tool. This methodology consists of two phases: development and application. In the development phase, an FCM is created for each group member and these are then merged to produce a group FCM. The application phase consists of static analysis of concepts and causal relationships, and dynamic analysis of the simulated system over time. Jetter and Sperry (2013) propose an FCM methodology in support of stakeholder engagement in product planning. Their method helps product planners to systematically capture, understand, and assess stakeholder needs and their interdependencies. Their approach consist

of six basic steps for organizing FCM modeling projects: Clarification of project objectives and information needs (Step 1); Plans for knowledge elicitation (Step 2); Knowledge capture (Step 3); Conceptual (Step 4) and detailed (Step 5) design of FCM; Test, Interpretation, and Validation of model results (Step 6). Jetter & Kok (2014) contend that such a six-step FCM modeling framework would be applicable in future studies to better integrate expert, stakeholder, and indigenous knowledge by creating scenarios that bridge the gap between quantitative analysis and qualitative story lines.

FCMs have been also used to develop a fuzzy cognitive agent to provide personalized recommendations to on-line customers (Miao et al., 2007). The agent learns users' preferences from the most recent cases and helps customers to make inferences and decisions. Xirogiannis and Glykas (2007) propose the application of the fuzzy causal characteristics of FCMs to generate a hierarchical and dynamic network of interconnected maturity indicators in e-business strategy formulation exercises. To improve semantic inference, Lee & Kwon (2014) propose an ontological semantic inference method that combines the CM and semantic influence. This approach reuses a pre-defined cognitive map and provides an ontological semantic inference mechanism in decision making environments by reducing the degree of cognitive complexities in a large cognitive map. Here, the predefined knowledge, which is represented as a CM, is processed through semantic inference method to enhance decision making.

Knowledge Creation

CM techniques have been applied for knowledge creation. Nonaka (1994) define the four "modes" of knowledge creation as 1) socialization: conversion of tacit knowledge to new tacit knowledge through interaction of individuals, sharing ideas and experiences and learning from each other; 2) externalization: conversion of tacit knowledge to new explicit knowledge such as articulation of best practices or lessons learnt; 3) combination:

conversion of explicit knowledge to new explicit knowledge by merging, categorizing, reclassifying and synthesizing existing explicit knowledge; 4) internalization: conversion of explicit knowledge to new tacit knowledge that could be achieved through the learning and understanding that result from reading about a specific topic.

Given that tacit knowledge is difficult to formalize and communicate (Polanyi, 1966), socialization, which occurs through conversion of such tacit knowledge to a new form of tacit knowledge, is a complex task to model. As a result, CMs have not been applied directly to model socialization mode of knowledge creation. However, the four aforementioned knowledge creation modes are interdependent and intertwined so that each mode relies on, contributes to, and benefits from the other modes (Alavi & Leidner, 2001). Hence, it is possible to use one or more intermediate conversion steps to model socialization using CMs. That is, conversion of tacit knowledge to a new explicit knowledge (i.e. externalization) and then converting the obtained explicit knowledge to a new tacit knowledge (i.e. internalization). We may need to use a combination mode before internalization, however.

CM allows modeling of mental models of decision makers, and it leads to clarification and structuring of the experts' thought processes when faced with ill-structured problems (Rodhain, 1999). Thus, CMs can be used as a means of externalization. For example, Rodhain (1999) uses CMs to extract business strategy mental models of managers for determining a portfolio of projects. Other pertinent applications include application of CMs to extract experts' tacit knowledge in order to forecast stock prices (Montazemi & Chan, 1990) and to analyze information requirements (Montazemi & Conrath, 1986).

FCM has been used in group decision making to construct a causal knowledge base in stock investment analysis (Lee & Kim, 1997), in electronic data interchange (EDI) controls (Lee & Lee, 2007), in technology road mapping (Amer

et al. 2015), and in scenario building (Kim et al., 2016) as a means of externalization, so that the resulting CMs could be transferred, managed and stored as explicit knowledge.

Individuals' CMs could be different in a specific domain because perceived attributes and/or perceived causal relationships of CMs may be different from one person to another. These differences between CMs, which are called *content difference* (Langfield-Smith & Wirth, 1992) exist because of different levels of individual experience and expertise. Langfield-Smith and Wirth (1992) propose quantitative measures for analyzing content difference between two or more CMs. These measures would assist in providing a more objective basis for qualitative analysis. Eden (2004) discusses the use of CMs as a qualitative method for structuring ill-structured decision problems. Wang (1996) uses neural network as a quantitative method to measure differences between CMs of individuals over time. The comparisons of CMs provide useful information for a decision maker when considering individual points of view. Providing such information can be considered as combination, and analyzing of this information by decision makers to get an insight into a given problem can be considered as the internalization mode of knowledge creation. León et al (2013) propose a model for analyses learning, clustering and aggregation of FCM of decision makers' cognitive change at different levels of abstraction.

Learning methods have been used to improve knowledge represented by means of FCMs. These learning methods include the non-linear Hebbian learning rule (Papageorgiou et al., 2003), genetic learning method (Stach et al., 2005), unsupervised learning technique (Papageorgiou et al., 2006), and Imperialist Competitive Learning Algorithm (ICLA) (Ahmadi et al., 2015). Improving the embedded knowledge of CMs through machine learning methods can be considered as combination mode of knowledge creation that can improve the user's tacit knowledge (i.e., internalization).

For example, Lee et al. (2002) propose a three-phased web-mining inference amplification (WEMIA) based on inference logic of FCM. The first phase is used to extract association rules, and based on the extracted rules in the second phase, corresponding FCMs are developed. The advantages of causal knowledge over association rules are that it can provide a more refined inference mechanism than can the association rules (Lee et al., 2002). The final phase is used to apply inference amplification procedures to the causal knowledge: to eliminate rule redundancy, to search for the directly and indirectly chained rules, and to amplify inferences about the logical relationships between rules. In this case, knowledge is created thanks to the conversion of some explicit knowledge (i.e. association rules) to another form of explicit knowledge (i.e. FCM), which is referred to as *knowledge combination*. Here, knowledge is improved by the use of inference methods to derive rich semantics which are suitable for and understandable by the decision maker. This is referred to as the *internalization mode of knowledge creation*.

Thus, CM techniques can be applied directly toward externalization and combination modes of knowledge creation and can contribute indirectly toward internalization and eventually to the socialization mode of knowledge creation.

FUTURE RESEARCH DIRECTIONS

This literature review shows diverse use of CM in the varied domain of decision making processes under uncertainty. We expect increased sophistication in capturing CM and its application in support of intelligent information systems. In particular, CM can play a major role in realizing the usefulness of the Semantic Web, which is the outgrowth of many diverse desires and influences, all aimed at making better use of the Web as it stands. The Semantic Web is portrayed as: 1) a universal library, to be readily accessed and

used by humans in a variety of information use contexts; 2) the backdrop for the work of computational agents completing sophisticated activities on behalf of their human counterparts; and 3) a method for federating particular knowledge bases and databases to perform anticipated tasks for humans and their agents. Intelligent agents can use CM of users to filter information from the Semantic Web, making it possible to manage organizational knowledge using Intranet and the vast resources available from the Internet.

CONCLUSION

Cognitive mapping techniques have been applied in design and development of intelligent information systems as a means of acquiring knowledge from domain experts, manipulating knowledge to create new contents, storing/retrieving knowledge for later use, and sharing knowledge between group members to deal with ill-structured decision problems. Successful applications of cognitive mapping methodologies reveal the efficiency and flexibility of these techniques, which can be potentially utilized by developers of intelligent information systems as follows:

- Providing a rich picture of ill-structured problems for decision makers,
- Facilitating group decision making through clear exchange of ideas and information,
- Dynamic systems in uncertain environments using fuzzy cognitive maps,
- Providing cognitive feedbacks to improve decision makers' decision processes when faced with ill-structured decision problems,
- Improving quality of conceptual modeling of systems, user-system interactions and usability of the resulting systems, and
- Better identifying end-users' information requirements and improve user-developer communications.

KEY TERMS AND DEFINITIONS

Cognitive Map: A representation of the relationships which are perceived to exist among the elements of a given environment.

Explicit Knowledge: Codified knowledge which refers to knowledge that is transmittable in formal and systematic language.

Fuzzy Cognitive Map: An extended and fuzzified version of the cognitive map that enables causal relationships to have fuzzy weights.

Knowledge Creation: The creation of new content based on the organizational tacit and explicit knowledge.

Knowledge Transfer: The transfer of organizational knowledge from one entity to another entity within/between organizations.

Tacit Knowledge: Personal knowledge which could be shared and exchanged through face-to-face contact among actors.

Computer-Assisted Parallel Program Generation

Shigeo Kawata

Utsunomiya University, Japan

INTRODUCTION

Parallel computation is widely employed in scientific researches, engineering activities and product development. Parallel program writing itself is not always a simple task depending on problems solved. Large-scale scientific computing, huge data analyses and precise visualizations, for example, would require parallel computations, and the parallel computing needs the parallelization techniques. In this Chapter a parallel program generation support is discussed, and a computer-assisted parallel program generation system P-NCAS is introduced.

Computer assisted problem solving is one of key methods to promote innovations in science and engineering, and contributes to enrich our society and our life toward a programming-free environment in computing science. Problem solving environments (PSE) research activities had started to enhance the programming power in 1970's. The P-NCAS is one of the PSEs; The PSE concept provides an integrated human-friendly computational software and hardware system to solve a target class of problems (Kawata, 2014). For example, a PSE generates a computer program automatically to solve differential equations (Boonmee et al., 1998a; Boonmee et al., 1998b; Fujio et al., 1998; Fujita et al., 2000; Gallopoulos, et al., 1991; Gallopoulos et al., 1994; Hirayama et al., 1988; Houstis et al., 1992; Kawata et al., 2000; Okochi et al., 1994; Rice et al., 1984; Umetani, 1985). In the PSE concept, human concentrates on target problems, and a part of problem solving, which can be solved mechanically, is performed by computers or machines or software.

The concept of the computer-assisted program generation has been opening the new style of the computer programing to reduce the programing hard task. Huge computer software may include errors and bugs. The errors or malfunction of the software infrastructure may induce uncertainty and accordingly serious accidents in our society (Einarsson, 2005; Kawata et al, 2012). The programing process tends to include mechanical parts, that means, mechanically programmable parts. When the application area of the software is limited in a reasonable size, a part of the software would be mechanically generated. For example, scientific research-oriented programs would have a similar program structure depending on the numerical scheme.

P-NCAS supports scientists and engineers to generate parallel programs for problems described by partial differential equations (PDEs). P-NCAS presents a remarkable capability of visualization and steering of all the processes required for the generation of parallel programs. In P-NCAS users input problem description information including PDEs, initial and boundary conditions, discretization scheme, algorithm and also comments on the problem itself as well as the parallelization information. P-NCAS supports a domain decomposition method for the parallelization, and the SPMD (single program multi data) model is employed. In P-NCAS users can see and edit all the information through the visualization and editing windows. The program flow is also visualized by a Problem Analysis Diagram (PAD). Even through the flow visualization window users can modify the program flow. Finally P-NCAS outputs the corresponding parallel program in the C language,

DOI: 10.4018/978-1-5225-2255-3.ch398

and at the same time a document for the program including the problem itself, the program flow, the PDEs, the initial and boundary conditions, the discretization method, the numerical algorithm employed and the variable definitions.

In this chapter first the PSE concept is briefly introduced, and then the details of the P-NCAS system is described for the parallel program generation support. Finally an example application result is presented including a load balancing result.

BACKGROUND OF COMPUTER-ASSISTED PROBLEM SOLVING ENVIRONMENT (PSE) IN SCIENTIFIC COMPUTING

PSE is defined as follows: “A system that provides all the computational facilities necessary to solve a target class of problems. It uses the language of the target class and users need not have specialized knowledge of the underlying hardware or software” (Gallopoulos, Houstis & Rice, 1994). In computing sciences, we need computer power, excellent algorithms and programming power in order to solve scientific and engineering problems leading to scientific discoveries and development of innovative new products. The computer power and the computing algorithms have been developed extraordinarily, and have provided tremendous contributions to sciences, engineering and productions. On the other hand, the programming power has not been developed well, compared with the computer power and the algorithm power. The concept of PSE was initially proposed to support the programming power in science and engineering, and has been explored for decades.

So far computer simulation has contributed to researches, productions and developments as well as experimental and theoretical methods. New researches tend to require new computer programs to simulate phenomena concerned. In developing new products engineers would also need new computer programs to develop new

products effectively. They may have to develop the new programs or learn how to use the programs for the product development. Human power still contributes greatly to develop and write the new computer software. They like to devote themselves to solve their target problems, but not to develop or learn the computer programs. The PSEs would also help them develop the computer software including parallel programs or learn how to use the software system.

In these days PSE covers a various wide area, for example, computer-assisted program generation, education support, CAE (Computer Aided Engineering) software learning support, grid/cloud computing support, factory management support including plant factory management, program execution support, uncertainty management in scientific computing, etc. There are many PSE examples studied so far. In the references of (Ford & Chatelin, 1987; Fujita et al., 2006; Gaffney, & Houstis, 1992; Houstis et al, 1997; Houstis, Rice, Gallopoulos & Bramley, 2000; Kawata, Tago, Umetani & Minami, 2005; Kawata et al., 2012; Kawata, 2014; Gaffney & Pool, 2007; Teramoto et al., 2007) one can find the example PSEs.

COMPUTER-ASSISTED PARALLEL PROGRAM GENERATION PSE - P-NCAS -

P-NCAS supports computer-assisted parallel program generation for PDEs-based problems in FDM (Finite Difference Method) based on a domain decomposition and MPI (Message-Passing Interface) functions (MPI, 2012). In addition, parallel programs generated in P-NCAS have load-balancing functions; one is a function for a static load balance and the other is that for the dynamic load balance. Figure 1 shows the P-NCAS work flow for the parallel program generation.

Through the interface of the PSE system of P-NCAS (Boonmee et al., 1998a; Boonmee et al., 1998b; Kawata et al., 2000; Fujita et al., 2000; Kawata, 2014) users input problem information

itself including PDEs, initial and boundary conditions, discretization and computation schemes, information for the domain decomposition and meanings for each equation and symbol. P-NCAS visualizes all the information to the users, and the users also can steer the program generation process through the P-NCAS interface. Then P-NCAS outputs a program flow, a C-language source code for the problem and also a document for the program and for the problem. In P-NCAS a user inputs his/her problem, and P-NCAS guides the users to solve the problem. The P-NCAS contains all the information of the problem, PDEs, the discretization scheme, the parallelization method, the mesh information, the equation manipulation method and results, the program structure designed, the variables employed, the constant definitions and the program itself. Therefore, P-NCAS also generates the corresponding document for the program generated in P-NCAS (Inaba et al., 2004).

P-NCAS helps users generate MPI-based parallel simulation programs based on PDEs (Fujita et al., 2000). P-NCAS supports a domain decomposition in a design of a parallel numerical simulation program, and the domain decomposition is designed or steered by users through a visualization window in P-NCAS. After designing the domain decomposition, the parallel program itself is designed and generated in P-NCAS, and the designed parallel program is visualized and steered by a Problem Analysis Diagram (PAD). In P-NCAS, MPI functions (MPI, 2012) are employed for the message passing, and a single program multiple data (SPMD) model is supported. The visualization and steering capabilities provide users a flexible design possibility of parallel programs.

Figure 2 shows an example image of the domain decomposition in P-NCAS. At least the boundary data for each domain decomposed are required to complete the computation in the adjacent processor (see Figure 3). In P-NCAS the MPI functions are also automatically inserted to complete the parallel data communication programming. After specifying the domain decomposition information in P-NCAS, the parallel program is generated and provided to the users.

The visualization and steering capabilities are enabled by the tree-type data structure shown in Figure 4 (Boonmee et al., 1998a) in P-NCAS. The tree-type data structure is employed to express all the data and information in P-NCAS including PDEs, each term of the PDEs, each symbol, boundary and initial conditions, the parallelization information for the domain decomposition and the program flow. Each PDE is discretized by a discretization method, which the user specifies. The equation algebraic manipulation is also performed smoothly based on the tree structure. In the tree-type structure each component has a link to its meaning. Based on the meanings and definitions of the components, P-NCAS helps users to prevent users' input or steering errors. When the users modify or steer the equation or one term of PDEs or some symbols, the steering results propagate and are reflected to all the relating components immediately through the links. By using the data structure, P-NCAS also visualizes easily all the information and provides the steering capability to users (see Figures 5-7).

Figure 5 presents an example description of an input problem information, and Figure 6 shows an example domain decomposition information. Through the P-NCAS visualization windows, for examples, shown in Figures 5 and 6, one can check all the information and can also edit the information. In P-NCAS, after setting all the information for the problem description, the discretization information and the parallelization information through the P-NCAS windows, all the information is visualized to the users and the users can edit all the information through the windows. The discretization of each PDE is also performed automatically; depending on the discretization information which users input through the P-NCAS windows, the PDEs are discretized and manipulated appropriately according to the PDEs solving scheme. Then P-NCAS designs the parallel program for the problem, and outputs the parallel program and the corresponding document. Figure 6 shows an example MPI program automatically generated in P-NCAS.

In addition, P-NCAS supplies users an option for a selection of a load balancing method, that is, an equal load balancing method or a dynamic load balancing method. When all the CPUs or machines are equivalent and the machine power is static, the equal load balancing method is appropriate. When the machines are heterogeneous or the machine power changes dynamically, the dynamic load balancing method is appropriate. Users can specify one of them, when they input the parallelization information through P-NCAS. In the dynamic load balance P-NCAS generates additional functions to measure all the machine power dynamically together with the corresponding computing program generated. The additional load balance measure functions measure the machine power regularly during the computation, and dynamically the domain sizes decomposed are modified to minimize the computation time.

Figure 8 shows an example parallelization performance result for a shock wave propagation in a 2-dimensional compressible-fluid simulation: a parallel program generated in P-NCAS is used to measure the parallelization performance. In Figure 8 the static load balance method is used on uniform machines. In order to check the dynamic load balance function automatically generated by P-NCAS, during the computation an additional load was applied as shown in Figure 9 (the left graph): by the additional load the computation time increases much in this specific case, if the static load balancing is used. When the dynamic load balancing method is selected in this example case, P-NCAS generates the functions, which measure the load balance of each machine dynamically, and according to the measured result each domain size is changed and adjusted dynamically to minimize the computation time. The right graph in Figure 9 demonstrates the viability of the dynamic load balancing functions generated in P-NCAS, and the computation time reduction is significant in this case.

FUTURE RESEARCH DIRECTIONS

At present P-NCAS supports the parallel program generation for PDEs-based problems by FDM based on the domain decomposition parallelization method and MPI. P-NCAS demonstrates that for a specific scientific problem area described by PDEs the parallel program generation is well supported mechanically by computers.

One of the near future works should be a parallel program generation support for FEM. FEM is also widely used in industries and scientific areas. One of future directions is a program generation support for specific computer architectures: a program generation support oriented to, for example, GPU computers or vector computers. GPU is now widely available, but it needs a special care for its programming. In addition to the directly relating areas to P-NCAS, a programming-free environment should be studied further to reduce the heavy task of the programming. So far one way has been to build CAE (Computer-Aided Engineering) software to reduce the programming work. P-NCAS and its future capabilities would contribute to build up CAEs. CAE is one of good ways to reduce the programming task. However, to learn how to use huge CAE softwares is another hard task, and this hard work should be also supported. On this point, PSE would also help users learn CAEs, and CAE-navigation PSEs help users learn or work on huge CAE systems.

Another important future direction must be to support scientific computing without uncertainty (Einarsson, 2005; Kawata et al., 2012; Kawata, 2014). In the process of scientific computing, the origin of uncertainty comes from physical model uncertainty, mathematical model errors, unknown input data, unknown boundary condition errors, numerical model errors, insufficient numerical precision, round-off error, floating point precision, programming errors, data processing errors or uncertainty, visualization errors, human errors, etc. So far the uncertainty or the errors in scientific

computing have caused serious accidents and disasters (Einarsson, 2005). Future PSEs should support to reduce the uncertainties in scientific computing.

CONCLUSION

We have presented a concept of computer-assisted parallel program generation, and the P-NCAS system is introduced. The PSE concept and a brief history of PSE research activities are also presented in computing science. The PSE researches have explored capabilities of enhancement of program-

ming power. PSEs have also started to provide a reliable tool to help engineers and scientists generate programs including parallel programs. There would not be an almighty PSE to solve all the problems, but each problem area would be solved by a specific PSE, for example, a PSE for a parallel program generation for PDEs-based problems by FDM and the domain decomposition; Another parallel program generation PSE would be needed for problems by FEM (Finite Element Method) or BEM (Boundary Element method) or particle methods, for example. A lot of PSE studies have demonstrated that each PSE in each area works well to support users to

Figure 1. P-NCAS work flow for the computer assisted scientific parallel program generation support. P-NCAS inputs the domain-decomposition parallelization information, partial differential equations (PDEs), initial and boundary conditions, discretization method and algorithm, and outputs a C language program. The PDEs are automatically discretized and the program is generated mechanically. P-NCAS is a white box system, in which users can see and steer all the processes of program generation. P-NCAS system contains all the information for program generation, including basic equations, discretization schemes, discretized equations, boundary and initial conditions, parallelization scheme, mesh structure, program structure, and definitions of variables and constants. Therefore, a document for the corresponding program is also generated together with the program itself.

Figure 9. A performance test result for a dynamic load balance. An additional load was applied during the computation, so that the computation time increases as shown in the left graph. When the dynamic load balancing function generated automatically by P-NCAS is used to this specific case, the domain size changes automatically depending on the machine load, and the result of the dynamic load balancing in the right graph shows the viability of the dynamic load balance functions generated by P-NCAS.

solve their target problems effectively. Even for uncertainty management in computing science PSE supports realistic tolls to avoid numerical errors or uncertainties (for example, Einarsson, 2005; Kawata et al., 2012).

In this Chapter we presented P-NCAS for the parallel program generation support, and the results shown demonstrate that the P-NCAS, a parallel program generation support system, works very effectively to solve the problems in parallel. The results in P-NCAS show that the PSE concept and P-NCAS are viable for the problem solving in computing science. PSEs would be appropriate to enhance the programming power and to reduce the costs and heavy tasks in scientific computing as a reliable society infrastructure.

KEY TERMS AND DEFINITIONS

Parallel Computing: Computations performed in parallel on distributed computers or processors. Parallel computing program needs a special treatment to divide computations into many sub-computations on the distributed computers or processors. Special parallel computers would need special programming technique to divide the task into many sub-tasks or to achieve the communication among processors or computers if needed.

PSE (Problem Solving Environment): Defined as “A system that provides all the computational facilities necessary to solve a target class of problems. It uses the language of the target class and users need not have specialized knowledge of the underlying hardware or software”. An example typical PSE generates a computer program automatically to solve differential equations. PSE provides integrated human-friendly computational services and facilities. At present PSE covers a rather wide area, for example, program generation support PSE, education support PSE, CAE software learning support PSE, grid/cloud computing support PSE, job execution support PSE, e-Learning support PSE, uncertainty management in scientific computing, and PSE for PSE generation support. A parallel computing support PSE, P-NCAS is introduced in this Chapter.

Scientific Simulation: Computation to describe a real world in computer.

Constrained Nonlinear Optimization in Information Science

William P. Fox

Naval Postgraduate School, USA

INTRODUCTION

A company manufactures new smart-phones that are supposed to capture the market by storm. The two main inputs components of the new smart-phone are the circuit board and the relay switches that make the phone faster and smarter and give it more memory.

The number of smart-phones to be produced is estimated to equal $E = 200x_1^{\frac{1}{3}}x_2^{\frac{1}{2}}$, where E is the number of smart-phones produced and x_1 & x_2 are the number of circuit board hours and the number of relay hours worked, respectively. Such a function is known to economists as a *Cobb–Douglas function*. Laborers are paid by the type of work they do: the circuit boards and the relays for \$5 and \$10 an hour, respectively. We want to maximize the number of smart-phones to be made if we have \$150,000 to spend on these components in the short run.

Lagrange multipliers can be used to solve *nonlinear optimization problems* (NLPs) in which all the constraints are equality constrained. We consider the following type of NLPs as shown by Equation (1):

$$\text{Maximize (Minimize) } z = f(x_1, x_2, \dots, x_n) \quad (1)$$

Subject to

$$g_1(x_1, x_2, \dots, x_n) = b_1$$

$$g_2(x_1, x_2, \dots, x_n) = b_2$$

...

$$g_m(x_1, x_2, \dots, x_n) = b_m$$

DOI: 10.4018/978-1-5225-2255-3.ch399

In our smart-phones example, we find we can build an equality constrained model. We want to maximize

$$E = 200x_1^{\frac{1}{3}}x_2^{\frac{1}{2}}$$

subject to the equality constraint

$$5x_1 + 10x_2 = 150,000$$

Problems in information science and technology such as this can be modeled using constrained optimization. We begin our discussion with equality constrained optimization, then discuss the inequality constrained optimization, and finally discuss some numerical methods to approximate the solutions.

BACKGROUND

The general constrained nonlinear programming (NLP) problem is to find x^* as to optimize $f(X)$, $X = (x_1, x_2, \dots, x_n)$ subject to the constraints of the problem shown in equation (2).

$$\text{Maximize or Minimize } f(x_1, x_2, \dots, x_n)$$

subject to

$$g_i(x_1, x_2, \dots, x_n) \begin{cases} \geq \\ = \\ \leq \end{cases} b_i \quad (2)$$

for $i = 1, 2, \dots, m$.

Classical constrained optimization appeared with equality constraints and Lagrange multiplier named for Joseph Lagrange in the late 1700's. It was almost two hundred years later when Kuhn-Tucker (1951) presented their famous Kuhn-Tucker (KT) conditions. Scholars later found that Karsuh (1939) had done considerable work on his thesis in the area of constrained optimization and thus, was added his name was added to create the Karsh-Kuhn-Tucker (KKT) conditions. Bellman (1952; 1957) created dynamic programming in the 1950's to handle sequential constraints in optimization.

Methods to ease computation and complexity of certain forms of NLP were created to ease the solving of such problems. Quadratic programming (Bazaraa et al., 1993) and Wolfe's method (1959) showed how to convert some NLPs into linear programs. Separable programming was another heuristic procedure described by Winston (2002) and Bazaraa et al. (1993). Complexities in problems have led to other heuristic models. The evolutionary strategy optimization technique was created in the early 1960s and developed further in the 1970s and later by Ingo Rechenberg, Hans-Paul Schwefel and his co-workers. Further development was done in evolutionary strategies by Michalewicz (1999). Strides in computer science led to the development of genetic algorithms, (Homaifar et al. 1994; Stender, 1994; Burke et al., 2005) and then to particle swarm optimization (Kennedy, 1995; 1997; Parsopolous et al., 2002). The complexity of the problems dictates the methods to be used. Cuckoo search is the most recent optimization method (Yeng et al, 2009)

MAIN FOCUS

Introduction and Basic Theory

To solve NLPs in the form of Equation (2), we associate a Lagrangian multiplier, λ_i , with the i th constraint and form the Lagrangian equation to get Equation (3):

$$L(X, \lambda) = f(X) + \sum_{i=1}^m \lambda_i (b_i - g_i(X)) \quad (3)$$

The computational procedure for Lagrange multipliers requires that all the partials of this Lagrangian function, Equation (4), must equal zero. These partials are the *necessary conditions* of the NLP problem. These are the conditions required for $\mathbf{x} = \{x_1, x_2, \dots, x_n\}$ to be a solution to Equation (3).

$$\text{The Necessary Conditions} \quad (4)$$

$$\partial L / \partial X_j = 0 \quad (j = 1, 2, \dots, n \text{ variables}) \quad (4a)$$

$$\partial L / \partial \lambda_i = 0 \quad (i = 1, 2, \dots, m \text{ constraints}) \quad (4b)$$

Definition: $\mathbf{x}$ is a regular point if and only if $\nabla g_i(x)$, $i = 1, 2, \dots, m$ are linearly independent.

Theorem 1

- Let (2) be a maximization problem. If f is a concave function and each $g_i(x)$ is a linear function, then any point satisfying Equation (4) will yield an optimal solution.
- Let (2) be a minimization problem. If f is a convex function and each $g_i(x)$ is a linear function, then any point satisfying Equation (4) will yield an optimal solution.

The Hessian matrix is used to determine if a function was convex, concave, or neither. We also note that the above theorem limits our constraints to linear functions. What if we have nonlinear equality constraints?

We can use the bordered Hessian in the sufficient conditions. Given the bivariate Lagrangian function as in

$$L(x_1, x_2, \lambda_i) = f(x_1, x_2) + \sum_{i=1}^m \lambda_i (b_i - g_i(x_1, x_2))$$

The bordered Hessian is

$$BdH = \begin{bmatrix} 0 & g_1 & g_2 \\ g_1 & f_{11} - \lambda g_{11} & f_{12} - \lambda g_{12} \\ g_2 & f_{21} - \lambda g_{21} & f_{22} - \lambda g_{22} \end{bmatrix}$$

We find the determinant of this bordered Hessian as Equation (5):

$$|BdH| = \det \begin{bmatrix} 0 & g_1 & g_2 \\ g_1 & f_{11} - \lambda g_{11} & f_{12} - \lambda g_{12} \\ g_2 & f_{21} - \lambda g_{21} & f_{22} - \lambda g_{22} \end{bmatrix} = g_1 g_2 (f_{21} - \lambda g_{21}) + g_2 g_1 (f_{12} - \lambda g_{12}) - g_2^2 (f_{11} - \lambda g_{11}) - g_1^2 (f_{22} - \lambda g_{22}) \quad (5)$$

The sufficient condition for a *maximum*, in the bivariate case with one constraint, is that the determinant of its bordered Hessian is positive when evaluated at the critical point. The sufficient condition for a *minimum*, in the bivariate case with one constraint, is that the determinant of its bordered Hessian is negative when evaluated at the critical point.

If x is a regular point and $g_i(x) = 0$ (constraints are satisfied) then $M = \{y | \nabla g_i(x) \bullet y = 0\}$ defines a plane tangent to the feasible region at x .

Lemma: If x is regular, $g_i(x) = 0$, and $\nabla g_i(x) \bullet y = 0$, then $\nabla f(x) \bullet y = 0$.

The Lagrange multiplier conditions are exactly the same for a minimization problem as a maximization problem. This is why these conditions alone are not sufficient conditions. Thus, a given solution can either be a maximum or a minimum. To determine whether the point found is a maximum, minimum, or saddle point, we use the Hessian.

The Lagrange multiplier, λ , has an important modeling interpretation. It is the “shadow price” for scarce resources. Thus, λ_i is the shadow price of the i th constraint. Thus, if the right-hand side (RHS) is increased by a small amount Δ in a maximize or a minimize problem, then the optimal solution will change by $\lambda_i \Delta$. We illustrate the shadow price both graphically and computationally.

Graphical Interpretation of Lagrange Multipliers

The method of a Lagrange multiplier has a geometric interpretation. This geometric interpretation involves the gradients of both the function and the constraints. Initially, let’s consider only one constraint,

$$g(x_1, x_2, \dots, x_n) = b$$

so that the Lagrangian equation simplifies to

$$\nabla f = \lambda \nabla g$$

The solution is the point in x where the gradient vector, $\nabla g(x)$, is perpendicular to the surface. The gradient vector, ∇f , always points in the direction in which f increases fastest. At both maximums and minimums, this direction must also be perpendicular to S . Thus, because both ∇f and ∇g both point along the same perpendicular line, then $\nabla f = \lambda \nabla g$. This is where the contours of the objective function are tangent to the constraints, see Figure 1.

Computational Method of Lagrange Multipliers with Applications

Consider the set of equations in Equation (3). This gives $m + n$ equations in the $m + n$ unknowns (x_j, λ_i) . Generally speaking this is a difficult problem to solve without a computer except for simple problems. Also, because the Lagrange multipliers are necessary conditions only (not sufficient), we may find solutions (x_j, λ_i) that are not optimal for our NLP. We need to be able to determine the classification of points found in the solution to the necessary conditions. Commonly used methods as justification include:

- the Hessian matrix or
- the bordered Hessian, $\text{Det}[BH] = 0$.

Example 1: Cobb-Douglass function

Figure 1. Equality constrained Lagrange multipliers for levels curves $f=5, 7, 8$, and 9

Recall the problem suggested in the introduction of the chapter. A company manufactures new smart-phones that are supposed to capture the market by storm. The two main inputs components to the e-phone are the circuit board and the relay switches. The number of smart-phones produced is estimated to equal $E = 200x_1^{\frac{1}{3}}x_2^{\frac{1}{2}}$ where E is the number of smart-phones produced and x_1 & x_2 are the number of circuit board hours and the number of relay hours worked, respectively. Such a function is known to economists as a *Cobb–Douglas function*. Our laborers are paid by the type work they do: the circuit boards and the relays for \$5 and \$10 an hour. We want to maximize the number of smart-phones to make if we have \$150,000 to spend on these components in the short run.

$$\text{Maximize } E = 200x_1^{\frac{1}{3}}x_2^{\frac{1}{2}}$$

subject to the equality constraint

$$5x_1 + 10x_2 = 150,000.$$

Using the method of Lagrange multipliers as described, we find we can make 434,388.51 in selling smart-phones using 12,000 relays and 9,000 circuit boards hours of labor with $\lambda = 2.4132$, see Figure 2. The Hessian is negative definite so we have found the maximum. If the constraint is increase by \$1, we can increase our profits by making 2.41 more smart-phones.

Figure 2. Equality optimization of smart-phone problem

INEQUALITY CONSTRAINTS: KARUSH-KUHN-TUCKER NECESSARY AND SUFFICIENT CONDITIONS

Introduction to KTC

In most realistic problems, many of the constraints are inequalities. These constraints form the boundaries for the solution. The general form of the NLP we present is shown by Equation (6):

$$\begin{aligned} &\text{Maximize (minimize) } z = f(x_1, x_2, x_3, \dots, x_n) \\ &\text{Subject to} \\ &g_1(x_1, x_2, \dots, x_n) \geq b_1 \\ &g_2(x_1, x_2, \dots, x_n) \geq b_2 \\ &\cdot \\ &\cdot \\ &\cdot \\ &g_m(x_1, x_2, \dots, x_n) \geq b_m \end{aligned} \quad (6)$$

One classic method for solving NLPs of this type, Equation (6), is the Karush-Kuhn-Tucker condition (KKTC).

Basic Theory of Constrained Optimization

During this discussion of KTC, we are concerned with problems of the form (6a): maximize or minimize $f(X) = f(x_1, x_2, \dots, x_n)$ subject to

$$g_i(x_1, x_2, \dots, x_n) \begin{cases} \geq \\ = \\ \leq \end{cases} b_i \quad (6a)$$

for $i = 1, 2, \dots, m$.

We allow the constraints to be equal and either less than or equal to or greater than or equal to. We have previously discussed Lagrange multipli-

ers to solve problems with equality constraints. Recall that with Lagrange multiplier the optimal solution actually fell on one constraint or at an intersection of several constraints. With the inequality constraints, the solution no longer must lie on a constraint or at an intersection point of constraints. This concept poses new problems. We need a method to account for the position of the optimal solution relative to each constraint. This KKTC procedure involves setting up a Lagrangian function of the decision variables $\mathbf{X}$, the Lagrange multipliers λ , and the slack or surplus variables $\mathbf{U}$. The $\mathbf{X}_j$ are the decision variables $(x_1, x_2, \dots, x_n)$, the $-\lambda_i$ are the shadow prices for the i th constraint, and the $\mathbf{U}_i$ are either added (slack variables from $\leq$ constraints) or subtracted (surplus variables from $\geq$ constraints). Thus, with the sign of $\mathbf{U}_i$ we are able to accommodate both $\leq$ and $\geq$ constraints.

We set up this generic Lagrangian function, equation (7):

$$L(X, \lambda, U^2) = f(X) + \sum_{i=1}^m \lambda_i (g(X_i) + (\pm U^2) - b_i) \quad (7)$$

U_i^2 depends on the type of inequality constraint, we either need to add or subtract a quantity U_i^2 to make the inequality into an equality. The computational procedure for the KTC requires that all the partials of this Lagrangian function equal zero. These partials are the *necessary conditions* of the NLP problem. These are the conditions required for $\mathbf{x} = \{x_1, x_2, \dots, x_n\}$ to be a solution to Equation (7).

$$\text{The Necessary Conditions} \quad (8)$$

$$\partial L / \partial X_j = 0 \quad (j = 1, 2, \dots, n) \quad (8a)$$

$$\partial L / \partial \lambda_i = 0 \quad (i = 1, 2, \dots, m) \quad (8b)$$

$$\partial L / \partial U_i = 0 \text{ or } 2U_i \lambda_i = 0 \quad (i = 1, 2, \dots, m) \quad (8c)$$

The following two theorems give the sufficient conditions for $x^* = \{x_1, x_2, \dots, x_n\}$ to be an optimal solution to the NLP given in Equation (8).

The Sufficient Conditions (9)

- (9a) **Minimum:** If $f(x)$ is a convex function and each of the $g_i(x)$ are convex functions, then any point that satisfies the necessary conditions is an optimal solution. An optimal point is a point that minimizes the function subject to the constraints. λ_i is greater than or equal to zero for all i .
- (9b) **Maximum:** If $f(x)$ is a concave function and each of the $g_i(x)$ are convex functions, then any point that satisfies the necessary conditions is an optimal solution. An optimal point is a point that maximizes the function subject to the constraints. λ_i is less than or equal to zero for all i .

If these above conditions are not completely satisfied, then we may use another method to check the nature of a potential stationary or regular point, such as the bordered Hessian.

Bordered Hessian

The bordered Hessian is a symmetric matrix of second partials of the Lagrangian:

$$H_B = \partial^2 L / \partial (X_j^2, \lambda_k^2) \{j = 1, 2, \dots, n, k = 1, 2, \dots, m\}$$

We can determine, if possible, the nature of the stationary point by classifying the bordered Hessian. This method is only valid leading to max or min points. If the bordered Hessian is indefinite, then another method should be used.

Complementary Slackness

The KTC computational solution process uses these necessary conditions for solving 2^m possible cases, where m equals the number of constraints. The value 2 comes from the possible conditions

placed on λ_i : It either equals zero or does not equal zero. There is actually more to this process because it really involves the complementary slackness condition embedded in the necessary condition, $2 U_i \lambda_i = 0$. Thus, either U_i equals zero and λ_i does not equal zero or U_i is greater than or equal to zero and λ_i is equal to zero. This ensures that the complementary slackness conditions are satisfied while the other necessary conditions from Equations 7a and 7b are solved.

It is these complimentary slackness necessary conditions, Equation 6c, that leads to the solution process on which we focus our computational and geometric interpretation. We have defined U_i^2 as a slack or surplus variable. Therefore, if U_i^2 equals zero, then our point is on the i th constraint; and if U_i^2 is greater than zero, then the point does not lie on the i th constraint. Furthermore, if the value of U_i^2 is undefined because it equals a negative number, then the point of concern is infeasible.

Computational KKTC With Information Science Application

Example 2: Revisit Cobb-Douglass, Smart-phones, with modifications

Recall the problem suggested in the introduction of the chapter. A company manufactures new smart-phones that are supposed to capture the market by storm. The two main inputs components to the e-phone are the circuit board and the relay switches. The number of smart-phones produced

is estimated to equal $E = 200x_1^{\frac{1}{3}}x_2^{\frac{1}{2}}$ where E is the number of smart-phones produced and x_1 & x_2 are the number of circuit board hours and the number of relay hours worked, respectively. Our laborers are paid by the type work they do: the circuit boards and the relays for \$5 and \$10 an hour. We want to maximize the number of smart-phones to make if we have at most \$150,000 to spend on these components in the short run. We also have capital restrictions on labor. These are:

\$2 for type x_1 and \$20 for type x_2 with a total available capital of \$125,000.

$$\text{Maximize } E = 200x_1^{\frac{1}{3}}x_2^{\frac{1}{2}}$$

Subject to:

$$5x_1 + 10x_2 \leq 150,000$$

$$2x_1 + 20x_2 \leq 125,000$$

$$x_1, x_2 \geq 0$$

Using the method of KKTC, we find we can make 356,513 smart phones by using 21875 and 4062.5 relays respectively. Further our two shadow prices are -0.2611 and -2.06 respectively, which imply that a 1 unit increase in total relays increases production by about 0.261 units while a \$1 increase in capital increases production by 2.06 units. Thus, we would prefer a \$1 investment in capital. Figure 3 shows the graphical analysis. The boarded Hessian is negative definite so we found the maximum.

Numerical and Heuristic Methods

Not all optimization problems are solvable in closed form. For that reason more and more procedures are created to solve these problems. Fox

(1990) presented a heuristic algorithm to solve a non-linear objective function with both linear and non-linear constraints as applied to component selection and user specification problems. Xanthopoulos et al. (2011) used a hybrid genetic algorithm to solve constrained optimization in Just-in-Time manufacturing systems in supply chain optimization. Homaifar et al. (1994) and Michalewicz (1991) developed algorithms for genetic algorithm to solve constrained optimization problems with good results. Alvarez-Vasquez et al. (2000) addressed the optimization of citric acid production rate.

Some classical methods include quadratic programming and separable programming methods that convert certain NLP into linear programs (see Bazaraa et al., 1993). Additionally newer numerical optimization method have been created such as simulated annealing, differential evolution, particle swarm optimization, genetic algorithms, and cuckoo search.

- **Quadratic:** Quadratic programming problems (QPP) is a special case of nonlinear optimization where the highest degree of x is squared. Several algorithms exist to solve QPPs.

Shim (1983) discussed some applications of QPP in business.

Figure 3. Graphical analysis of example 2.

- **Separable:** Separable programming is a another special case of nonlinear optimization where we might use approximating functions with piecewise linear functions. Stefanov (2001) presents a good discussion separable programming.
- **Feasible Directions:** This method was invented in 1960 by Zoutendijk and many revisions have been made to improve it over the years. Fox et al. (1993) showed a method of starting points to improve convergence for some of these methods such as feasible directions. Canale (2010) has a good summary of these methods.
- **Particle Swarm Optimization (PSO):** This is a computational method that solves the problem by iteratively trying to improve the candidate solution that was discovered by Kennedy and Eberhart in 1995, and modified by Shi in 1998.. It used a population of candidate solutions, called particles, and moves them around the search space. This is expected to move the swarm toward the best solutions. It was founded for simulating social behavior thus lends itself nicely to information science. Good example are found in Bonyadi et al (2016).
- **The Nelder–Mead Method** is a commonly applied numerical method used to find the minimum or maximum of an objective function in a multidimensional space. It is applied to nonlinear heuristic optimization method in problems for which derivatives may not be known. The Nelder–Mead technique was devised by Nelder and Mead (1965).
- **Simulated Annealing (SA)** is a probabilistic technique for approximating the global optimum of a given constrained optimization problem that was described by Scott Kirkpatrick, C. Daniel Gelatt and Mario P. Vecchi in 1983. Specifically, it is a meta-heuristic to find good approximate global optimization solution in large search spaces.. It is often used when the search space is discrete (e.g., all tours that visit a given set of cities). For problems where finding the precise global optimum is less important than finding an acceptable local optimum in a fixed amount of time, simulated annealing may be preferable to other alternatives. Simulated annealing interprets slow cooling as a slow decrease in the probability of accepting worse solutions as it explores the solution space. Accepting worse solutions is a fundamental property of metaheuristics because it allows for a more extensive search for the optimal solution.

Table 1. Free and Open Source software

Name	License	Brief information
ADMB	BSD	nonlinear optimization framework, using automatic differentiation
APMonitor	BSD	MATLAB Toolbox and Python APIs to Mixed Integer Nonlinear Programming Solvers
ASCEND	GPL	mathematical modeling system
IPOPT	CPL	large scale nonlinear optimization for continuous system
JOptimizer	ASL	open source java library for convex optimization
OpenOpt	BSD	free numerical optimization framework for solving NLP, LP, MIP, QP, with automatic differentiation features.
OpenSolver	GPL	open source Excel addin for solving LP and MIP problems
OPTI Toolbox	BSD	MATLAB Toolbox for solving linear, nonlinear, continuous and discrete optimization problems.
MOEA Framework	LGPL	open source Java library for multi-objective optimization

For Proprietary software, see http://en.wikipedia.org/wiki/List_of_optimization_software.

- **Genetic Algorithms:** In the field of artificial intelligence it is a search heuristic that mimics the process of natural selection. This heuristic is routinely used to generate useful solutions. Genetic algorithms belong to the larger class of evolutionary algorithms (EA), which generate solutions to optimization problems using techniques inspired by natural evolution.
- **Cuckoo Search (CS)** was developed by Yang and Deb (2009). It was inspired by the cuckoo and how they lay their eggs in nests hosted by other birds. Some host birds can engage direct conflict with the intruding cuckoos. For example, if a host bird discovers the eggs are not their own, it will either throw these alien eggs away or simply abandon its nest and build a new nest elsewhere. Cuckoo search idealized such breeding behavior, and thus can be applied for various optimization problems.

Other techniques worthy of consideration are differential search and random search methods which can be found in optimization books.

Technology

There exist many software packages to assist with solving constrained, nonlinear optimization problems. These include and are not limited to LINGO, MAPLE, MATLAB, MATEMATICA, and EXCEL's (SOLVER). We provide a very abbreviated list below of other free software: (from http://en.wikipedia.org/wiki/List_of_optimization_software.)

FUTURE TRENDS

As problems get more complex, the need for more sophisticated and easy to use software will be sought that solve these difficult and complex problems quickly and allow for good sensitivity analysis.

CONCLUSION

We provided a survey of techniques to solve constrained optimization problems in information science and technology.

KEY TERMS AND DEFINITIONS

Binding Constraint: A constraint that is satisfied at equality.

Constraints: A resource constraint is one that either limits the amount of a resource or sets a minimum to amount of a resource requirement.

Decision Variables: The variables that change that affect the solution.

Feasible Region: The convex region bounded by the constraints.

Initial Values: Starting values for numerical methods. Default values are usually all 0's or all 1's but care must be taken to insure convergence.

Kuhn-Tucker: A nonlinear optimization methodology that involved inequality constraints.

Lagrange: A nonlinear optimization methodology that involved equality constraints.

Lagrange Multiplier: The Lagrange multiplier, λ , is used in sensitivity analysis in optimization problems. In general the objective function changes by the value of λ for each unit change in the resource.

Numerical Methods: When a function cannot be solved in closed form an appropriate numerical technique may be used to approximate the solution.

Optimization: The process of maximizing or minimizing an objective function.

Decimal Hardware Multiplier

Mário Pereira Vestias
INESC-ID/ISEL/IPL, Portugal

INTRODUCTION

IEEE-754 2008 has extended the standard with decimal floating point arithmetic. Human-centric applications, like financial and commercial, depend on decimal arithmetic since the results must match exactly those obtained by human calculations without being subject to errors caused by decimal to binary conversions. Decimal Multiplication is a fundamental operation utilized in many algorithms and it is referred in the standard IEEE-754 2008. Decimal multiplication has an inherent difficulty associated with the representation of decimal numbers using a binary number system. Both bit and digit carries, as well as invalid results, must be considered in decimal multiplication in order to produce the correct result.

This article focuses on algorithms for hardware implementation of decimal multiplication. Both decimal fixed-point and floating-point multiplication are described, including iterative and parallel solutions.

BACKGROUND

Usually, humans perform arithmetic operations using decimal arithmetic. However, computers do it with binary arithmetic. It means that performing decimal operations in a computer without support for decimal arithmetic is subject to errors from representing decimal numbers, converting them and rounding. In fact, it is easy to find decimal numbers that cannot be represented exactly in binary format (e.g., 0.1). Several examples exist where errors due to binary calculation of decimal numbers are obtained. A clarifying example came from the Vancouver Stock Exchange (Quinn, K.,

1983), where due to rounding errors an initial index value of 1000.000 dropped to 574.081 instead of the correct result of 1098.892.

In fact, the business and commercial markets were one of the triggers for the importance of decimal computer arithmetic since many commercial databases have more than 50% of the numerical data represented in decimal (Tsang, A. & Olschanowsky, M., 1991). In these cases, to avoid errors with undesirable consequences it is important to have a complete system to support decimal arithmetic.

At the era of electronic computers, both binary and decimal arithmetic functions were considered. We had computer systems, like the ENIAC (Goldstine, H. & Goldstine, A., 1996) and IBM 650 (Knuth, D., 1986) implementing arithmetic functions in decimal, and others like EDSAC (Wilkes, M., 1997) and EDVAC (Williams, M., 1993) that adopted binary based arithmetic implementations. Both arithmetic systems were still considered after the advent of transistorized computers with decimal numbers represented with four bits following different representations, like in Binary-Coded Decimal (BCD) format. However, soon binary arithmetic was adopted by most computer systems since at that time scientific computing, whose operations could be more efficiently implemented in binary, were more in demand than financial computing that requires decimal arithmetic to avoid costs from representation errors. So, binary became very popular, while decimal was supported only by some computers in the 1960s and 1970s.

Precise decimal arithmetic operations with binary based computing systems are done in software. In some cases, these binary-based computing systems include some specific hardware

DOI: 10.4018/978-1-5225-2255-3.ch400

instructions that are hardware supported and so software algorithms can take advantage of them to speed-up execution. Several languages include primate decimal datatypes, including Ada, COBOL, and SQL. Several other languages support the GDAS (General Decimal Arithmetic Specification) (Cowlshaw, M., 2008), including the IBMCDecNumberLibrary (Cowlshaw), the Java BigDecimal (Sun Microsystems), Eiffel Decimal Arithmetic (Crismer), Python Decimal (Batista), among others. Decimal floating point extensions conforming to the IEEE 754-2008 standard were proposed for C (JTC 1, 2007) and C++ (JTC 1, 2008) languages. These extensions were supported by GNU C compiler 4.2 release. Intel has also developed a decimal floating-point math library (Intel) that implements decimal floating-point arithmetic specified in IEEE 754-2008.

Hardware support for decimal arithmetic is needed if the percentage of time spent executing decimal functions from these software libraries is relevant. Two different perspectives have emerged in the end of the last decade. Wang (Wang, L.-K., et al., 2007), examined several financial benchmarks and concluded that the time spent on executing decimal operations ranged from 33.9% to 93.1%. On the contrary, a research from Intel (Cornea, M. & Crawford, J., 2007) concluded that most commercial applications spend less than 5% executing decimal operations. Therefore, hardware for decimal arithmetic is not a priority in the design of Intel's processors. In fact, Intel x86 processors offer only a set of eight fixed-point decimal arithmetic instructions, and Motorola 68K reduces this set to just five instructions. On the other side, several IBM's processors include a considerable support for decimal arithmetic. The S/390 processor (ESA/390, 2001) includes a dedicated decimal adder to execute decimal fixed point addition, subtraction, multiplication and division. The last two, are executed iteratively using additions and subtractions. The IBM System z9 (Duale, A. et al., 2007) and System z10 (Schwarz, E., Kapernick, J., & Cowlshaw, M., 2009) already include a decimal floating-point arithmetic unit

in conformance with IEEE 754-2008 standard. The GNU C Compiler (GCC) 4.3 Release and several compilers from IBM (e.g., IBM XL C/C++ (IBM)) were extended and developed to utilize the dedicated instructions and hardware units present in these IBM's processors.

DECIMAL MULTIPLICATION

Hardware implementations for decimal multiplication can be classified according to the type of operands to be multiplied as fixed or floating-point, whether the operands are fixed or floating-point, respectively.

Fixed-point multiplication follows generically the typical hand process that starts by generating partial products, followed by reduction of the partial products using decimal addition. The process can be either based on iterative or parallel algorithms. In the iterative approach partial products are generated and accumulated step-by-step in an iterative process, while in the parallel case partial products are generated in parallel and merged with an adder tree.

Decimal floating-point multiplication typically uses a fixed-point decimal multiplier to multiply the trailing significant fields, together with exponent addition, rounding and sign calculation, similar to a binary multiplier.

Designs for both fixed- and floating-point multipliers were proposed in different target technologies: Application Specific Integrated Circuit (ASIC) and Field Programmable Gate Arrays (FPGAs). FPGA-based solutions are flexible and can be configured with different operand sizes. Many existing solutions are optimized for specific technologies and therefore may not be the most appropriate solution when migrated from one technology to the other.

In the following, the basic algorithms and architectures of each type of decimal multiplier are introduced together with state-of-the-art proposals based on each of these types and technologies.

DECIMAL FIXED-POINT MULTIPLICATION

Whether in the iterative or in the parallel method, partial product generation in a fixed-point multiplication can be either the result of digit by digit, digit by word or word by word multiplication. In a digit by digit multiplication process each digit of the multiplier is multiplied by a digit of the multiplicand. A faster approach is to multiply each digit of the multiplier by the whole multiplicand, that is, a multiple of the multiplicand is accumulated for each digit of the multiplier. Word by word multiplication is a method that seeks to reduce the number of partial products at the cost of more complex partial product generation.

Digit by Digit Multiplication Design

Different designs are obtained for digit by digit iterative multiplication depending on the how the digits are traversed. One approach consists on multiplying a digit of the multiplier by all digits of the multiplicand from the least significant digit to the most significant digit. Thus, the multiplier must run all digits for each digit of the multiplier (see figure 1a).

At each step, a new digit by digit product must be added to the accumulated partial product using an n digit adder. Also, the partial product must be aligned right after multiplying a digit of the multiplicand and realigned left for each new digit of the multiplier

One of the disadvantages of this approach is that we need an n digit adder. A different approach consists on choosing the digits of the multiplicand and of the multiplier to be multiplied at each step so that the digits of the product are obtained in order from the least significant digit. For example, consider the multiplication of $A = A_1A_0$ and $B = B_1B_0$, the method calculates the product in the following order:

$$A \times B = A_0 \times B_0 + (A_0 \times B_1 + A_1 \times B_0)10 + (A_1 \times B_1)100$$

In the example, after the first $A_0 \times B_0$ multiplication, the partial product is shifted. Then, accumulate all digit by digit products with weight 10 and shift. Finally, accumulate the final product with weight 100.

The algorithm requires a more elaborate control over the shifts since the partial product only

Figure 1. Digit by digit multiplier with each digit of the multiplier multiplied by all digits of the multiplicand. a) Iterative and b) Parallel

shifts after accumulating all products of the same weight. On the other side, the width of the adder just has to be enough to accumulate all products of the same weight, that is, $\log_{10}(n \times 9^2)$ digits, where n is the number of digits of the multiplier.

In a digit by digit parallel design all digit products are generated in parallel and then accumulated using some form of adder tree (see Figure 1b). The solution requires more hardware, but it is faster. Considering the multiplication of $n \times n$ digits, the digit by digit method runs in $n \times n$ steps, while with the parallel approach all partial products are generated in a single and the same cycle followed by some more cycles to add all partial products.

Either iterative or parallel an important aspect in a digit by digit approach is how to multiply a digit by a digit. The product is either obtained from a lookup table or from an implementation with random logic. A closer look at the possible products reveals that from the total of 100 possible input combinations there are only 37 possible products. This redundancy can be reduced by recoding the digits of the operands. One such example illustrating the advantages of recoding was proposed in (Carlough, S., & Schwarz, E., 2006) and (Erle et al., 2005) with the digit range $\{-5, -4, -3, -2, 0, -1, 1, 2, 3, 4, 5\}$ which produces only 15 different unsigned products.

Only a few works have followed a digit by digit multiplication approach to design decimal multipliers. In (Larson, R., 1973) and (Ueda, T., 1995), digit by digit product is implemented with a lookup table. While in (Jaberipur, G. & Kaivani, A., 2007) the product is generated with combinational logic. The problems associated with this approaches are the complexity associated with generation of a digit by digit multiplier, which in a parallel solution requires a considerable amount of logic, and the number of cycles required in an iterative solution.

Digit by Word Multiplication Design

A faster approach for decimal multiplication is to multiply each digit of the multiplier by the whole multiplicand, that is, a multiple of the multiplicand is accumulated for each digit of the multiplier (see word by digit multiplier in Figure 2).

The multiples of the multiplicand may be generated on the fly or a priori and stored. Usually, only a subset of the ten possible multiples are generated and then added to generate the complete set of multiples. In (Busaba, F., 2004) even multiples are precomputed $\{2X, 4X, 6X, 8X\}$ and stored. The odd multiples are generated from the even multiples adding X . In (Erle, M. and Schulte, M., 2003) the multiples $\{X, 2X, 4X, 5X\}$ are precomputed. These multiples have the

Figure 2. Digit by word multiplier. a) Iterative and b) Parallel

advantage of being calculated without carry propagation. In (Vazquez, A. et al., 2007) the multiplier is based on signed-digit radix-10 recoding of the multiplier and precomputation of multiples $\{-5X, -4X, \dots, -X, 0, X, \dots, 4X, 5X\}$. The partial products are added using a BCD 4221 carry-save adder. This work has been followed in (Vázquez, A., Antelo, E. & Bruguera, J., 2014) other redundant codes, namely BCD excess-3 and an overloaded BCD representation. In (Lang, T. & Nannarelli, A., 2006) the multiplier is recoded to a signed digit representation as $Y_i = Y_H \cdot 5 + Y_L$, with $Y_H \in \{0, 1\}$ and $Y_L \in \{-2, -1, 0, 1, 2\}$. In this case, only multiples $2X$ and $5X$ have to be generated and a $10'$ complement to generate negative multiples. The method generates two partial products for each multiplier digit.

A few iterative digit by word multipliers have been proposed. In (Fukuta, M., 1987) the multiplicand is iteratively multiplied by one digit of the multiplier to generate a partial product. Partial products are then added to produce the final decimal product. Other decimal multipliers have been proposed based on sequential units, such as (Kenney, R., Schulte, M., & Erle, M., 2004) and (Erle, M. & Schulte, M., 2003), where a set of multiplicand multiples is generated in a preprocessing step and then selectively added according to the value of the multiplier digits. (Kaivani, A., Chen, L., & Ko, S., 2012) proposes a high frequency sequential multiplier using a fast carry-save adder. Sutter et al. (Sutter, G., et al., 2009) also propose an iterative decimal multiplier using an $N \times 1$ BCD multiplier and a BCD carry chain adder that accumulates the partial results in FPGA. Véstias in (Véstias, M., & Neto, H., 2011) proposed an iterative approach based on binary arithmetic also in FPGA.

Many more approaches have considered a parallel approach (Dadda, L. & Nannarelli, A., 2008), (Jaberipur, G. & Kaivani, A., 2009), (Vázquez, A., Antelo, E. & Montuschi, P., 2010), (Guardia, M., 2012), (Véstias, M. & Neto, N., 2012), (Han, L. & Ko, S.-B., 2013), (Zhu, M., Baker, A. & Jiang, Y.,

2013) using some different internal representations and different tree adders in both technologies.

Word by Word Multiplication Design

Considering word by word multiplication as the case in which a partial product results from the multiplication of more than one digit from the multiplier and from the multiplicand, the typical approaches that consider multiples generation of the multiplicand does not apply.

Considering word by word multiplication an approach was considered in (Neto, H. & Véstias, M., 2008) and extended in (Véstias, M. & Neto, H., 2010) using binary arithmetic implemented in FPGA. The decimal operands are first converted to binary, multiplied in binary and then the result is converted back to decimal (see example with 8-digit operands in Figure 3).

In the example, 8-digit operands are converted to binary. The result is a 27-bit number. A 27×27 multiplier produces a 54-bit product to be converted to a 16-digit number. Digits of the

Figure 3. Decimal multiplier using a binary multiplier

multiplier and the multiplicand can be grouped (e.g., 8-digit operands can be grouped in two 4-digit numbers and then partially multiplied as 4×4) in which case several partial products are generated. This method can be implemented as iterative or parallel. This approach is particularly attractive when binary multipliers are available, like in a microprocessor or in an FPGA where embedded binary multipliers are available. A major problem of this solution is that binary to decimal conversion is a slow process using the shift and add-3 algorithm. For large numbers, a fast parallel implementation of this algorithm consumes a considerable amount of hardware resources. Recently, Neto and Véstias (Neto, H. & Véstias, M., 2008) have proposed a new binary to decimal converter that is faster and uses about half of the resources when compared to the traditional shift and add-3 algorithm. With this new converter, the decimal multiplication using binary multipliers becomes quite competitive with the more common approaches based on direct decimal manipulation. A similar contribution was done in (Juang T.-B.; Chiu Y.-M. (2013) with a new high-speed binary to BCD converter for decimal multiplication.

DECIMAL FLOATING-POINT MULTIPLICATION

Decimal floating-point (DFP) multiplication has been proposed and implemented many years ago. For example, the IBM Type 1620 computer already considered variable precision decimal floating-point features. But it was only recently that decimal floating-point formats were standardized with the published IEEE 754-2008 standard. This brought a set of proposals for designing decimal floating-point units including multiplication.

IEEE 754-2008 Standard

IEEE 754-2008 published in August, 2008, defines three binary and two decimal floating-point

number formats. The inclusion of DFP format was probably the most relevant aspect considered in the standard.

While in the binary floating-point format (BFP) the operands and the result must be normalized, in the DFP format these do not have to be normalized. Hence, considering a number with precision p , a product with $p - m$ digits will have m different equivalent representations, as long as the exponent has sufficient range to allow the shift of the leading or trailing non-zero digits. For example, using 4 digits of precision, the number 45×10^8 can be represented as 450×10^7 or 4500×10^6 . This flexibility has led to the introduction of the concept *preferred exponent*. In case of the multiplication, the *preferred exponent* of $A \times B$ is $(E^A + E^B)$.

IEEE 754-2008 defines three formats for DFP: *decimal32*, *decimal64* and *decimal128*. Data in each format is encoded in three fields: (1) one bit sign S ; (2) a combination field G and (3) a trailing significand field. The trailing significant field represents all decimal digits of the number, except the most significant. Decimal digits in the field are either encoded in *Densely Packed Decimal* (DPD) format (M. F. Cowlishaw, 2002) or in *Binary Integer Decimal* (BID) format. The DPD encoding is a specific format to compress three decimal digits into 10 bits, instead of the 12 bits required using simple Binary Coded Decimal.

The operations specified in the standard include addition, subtraction, multiplication, division, square-root and fused multiply-addition; two new decimal operations: samequantum and quantize, used for exact computations; comparisons; and different types of conversions.

Five rounding modes are considered in the standard and also five exceptions (see IEEE 754-2008 standard for further details).

Floating-Point Multiplication Design

Decimal floating-point multiplication typically uses a fixed-point decimal multiplier to multiply

the trailing significant fields, together with exponent addition, rounding and sign calculation. The preferred exponent rule, for exact results, is Q_x (exponent of x) + Q_y (exponent of y). As in the binary case, exactness may be computed by normalizing the product and check the round and sticky bits. Another strategy to check the exactness is to predict if the sum of leading zeros (LZ) of both multiplier and multiplicand is larger than the number of digits of each operand. This is generally the common case and thus the product is exact, the calculated exponent is correct and needs no normalization. Otherwise, if the result is inexact or too large to be representable with the preferred exponent then the result of the multiplication needs to be normalized and then rounded (see Figure 4).

In a typical implementation, the operands are first unpacked to extract the sign, the exponent and the significand field. The signs of both operands are XORed to determine the sign of the product. The exponents are added and the significand fields are multiplied. The product is normalized with a left shift of $\min(LZ_x + LZ_y, \text{operands size})$ to remove the

leading zeros up to the operands size. The output of the integer multiplier is rounded, the exponents are adjusted according to the rounding requirements and the product is packed again from BCD to decimal floating-point format.

There are implementations of decimal floating-point multipliers in commercial microprocessors from IBM, namely Power6 (Eisen, L., et al., 2007) and z10 (Webb, C., 2008). Both architectures use the same word by digit integer multiplier. The implementation improves the execution of decimal multiplication compared to software solutions, but is relatively slow compared to binary multiplication since the multiplication is iterative. A slightly faster iterative floating-point multiplier compliant with IEEE 754-2008 was proposed in (Erle, M., et al., 2007) and a faster solution was proposed in (Hickman, B., et al, 2007) based on a fixed-point parallel multiplier. In (Navarro, G.; et al., 2013), a multiplier that operates on binary integer decimal (BID) encoded decimal floating-point (DFP) numbers is proposed. The multiplier is compliant with the IEEE 754-2008 Standard.

FUTURE RESEARCH DIRECTIONS

Decimal multiplication is an important operation for applications where errors are generated from representing the decimal numbers in binary are unacceptable. Decimal multiplication and, in general, decimal arithmetic has not received much attention until 1990s. Now, this field of research is getting much attention and became a hot topic of research.

In particular, decimal multiplication is already part of some commercial processors with dedicated decimal arithmetic instructions. However, the area still needs a set of real benchmarks to help us determine how far should we go about dedicated decimal arithmetic hardware, and in particular, decimal multiplier. What gains can be achieved with dedicated decimal multipliers and this influences the performance of binary arithmetic.

In fact, the integration of decimal arithmetic units with binary arithmetic units deserves further research. How to best integrate decimal hardware into an existing binary arithmetic unit is also an open question. A few solutions already combine decimal floating-point and binary floating-point in a single arithmetic unit (Tsen, S., 2009). Combining decimal and binary arithmetic is advantageous in terms of area but degrades the performance of binary multiplication. Therefore, it is expected to find combined decimal/binary multipliers to have latencies and throughputs close to those of isolated binary multipliers. The emphasis to achieve such similarities should be on the carry save adders used to add partial products so that the binary carry save adder can be used for both radices.

Decimal multiplication based on binary arithmetic also needs further research since it would be possible to integrate binary/decimal converters, a decimal multiplier and a binary multiplier in a single unit. Efficient binary/decimal converters are a decisive aspect for the success of this approach. Binary-based decimal multiplication is a type of combined binary/decimal operation and should be further researched. Processors or devices where binary multipliers are available can

be easily extended with decimal multiplication by using dedicated binary to decimal and decimal to binary converters in hardware or in software. Up to date, hardware for conversions between binary and decimal introduce a considerable delay in the execution time of the operation and so, decimal multiplication based on binary arithmetic is still slower than decimal based multipliers. However, further research over binary-decimal converters may change the scenario.

Word-by-word multiplication should be further investigated since it potentially reduces the number of partial products and consequently the complexity of the adder tree, including its layout routing. The problem has to do with the generation of partial products from multiples of the multiplicand with more than a single digit.

Iterative solutions are attractive since they reduce considerably the area of the design. However, even digit-by-word iterative multiplication may be too costly in terms of latency. Hence, iterative word-by-word solutions where words represent a group of digits should be further considered as a way to reduce latency while keeping an acceptable design area.

Fused operators must also be further investigated. For example, the fused multiply-add operation is very common and specified in the IEEE 754-2008 standard. But, only a few works have considered this problem. Therefore, this operations needs to be explored both in the context of a processor and also as a dedicated hardware fused unit.

Most general-purpose processors still do not include explicit hardware support for the main decimal operations since most of the generic applications they are supposed to execute are binary-based. A different approach could consider an application specific processor for decimal-based applications or an heterogeneous solution with a general-purpose processor and an FPGA that can be reconfigured to run any operation or function with decimal arithmetic. This solution can be easily achieved and have shown very good speed-ups when running decimal arithmetic.

Extended decimal precision arithmetic is still very immature and needs further research at least to consider the decimal128 format of the standard. Some previous decimal multipliers are scalable and can therefore be easily extended to support this format. Once again FPGAs are very attractive to implement high-precision multiplication not only with 128 digit operands but also any other number of digits.

CONCLUSION

The article describes the backgrounds of fixed and floating-point decimal multiplication. The typical architectures of both iterative and parallel multipliers are explained and state-of-the-art implementations for each solution are provided, including some recoding techniques to get faster or smaller implementations.

A considerable number of publications, patents and implementations have appeared during the last 50 years about binary arithmetic. On the other side, decimal arithmetic hardware is still in its infancy but already achieved very interesting results compared to those on binary arithmetic. Hardware designers for decimal arithmetic want to narrow the performance gap between decimal and binary arithmetic so that applications start using more decimal operations. So, the research about decimal multiplication, in particular, is an actual topic of research.

Recent publications proposed new operand recoding and new methods for binary to decimal conversions to improve the delay of decimal hardware multipliers. Therefore, both approaches are still considered, that is, direct decimal multiplication and binary-based decimal multiplication.

Whether decimal operands should be integrated with processors or in co-processing devices, like FPGAs, is also an open research question. If not used in processors, all decimal multiplier proposals will only be used as hardware blocks in some dedicated hardware implementation.

KEY TERMS AND DEFINITIONS

Binary-Coded Decimal: A binary code of decimal numbers where each digit is represented with four bits.

Decimal Fixed-Point Multiplication: Refers to the multiplication operation where the inputs are represented in radix ten fixed-point numbers.

Decimal Floating-Point Multiplication: Refers to the multiplication operation where the inputs are represented in radix ten real numbers.

Decimal Multiplication: Refers to the multiplication operation where the operands are represented with some decimal digit encoding.

Densely Packed Decimal: An encoding scheme in which three BCD digits are represented with ten bits.

Iterative Decimal Multiplication: A decimal multiplication method where partial products are generated and accumulated step-by-step in an iterative process.

Parallel Decimal Multiplication: A decimal multiplication method where partial products are generated and added according to a parallel process.

Digital Divide

Patrick Flanagan

St. John's University, USA

INTRODUCTION

Since 1991 when the World Wide Web (WWW) was first made available to the public, the WWW has revolutionized the ways the global community engages each other economically, politically, and socially. Its impact has been historically unprecedented. While the availability of and access to the WWW appears to be ubiquitous, it is not. The expansion of this marvelous Information Communication Technology (ICT) has not penetrated certain areas of the world resulting in a “digital divide.” This chapter discusses this digital divide. It first defines the term and how scholars have understood the digital divide. It then moves to discuss the origins of the term in popular literature and official government documents. From there, the chapter moves to present concrete evidence of how the digital divide has negatively impacted the global community. Finally, it names and evaluates the efforts of different organizations and agencies to resolve the digital divide. It concludes with a prospectus on the future challenges of information communication technology vis-à-vis the digital divide.

BACKGROUND

The digital divide is a term that describes the gap between those who have access to information communication technology (ICT) and those who have limited or no access. This distinction, however, between the “haves” and the “have nots” can be too basic a delineation (Compaine, 2001; Hawkins, 2006; Selwyn, 2004; Warschauer, 2002). What is “had” and “not had” is much more compre-

hensive involving available physical equipment, utility resources (for instance, electricity), and technological skills. While the “have nots” can be those who do not have effective access to information communication technology, the “haves” can include those who have a computer, but with no or limited connection to the Internet, with a rather dated dialup and not a broadband connection, or those who connect through a mobile phone. ICT has transformed significantly political, social, and economic engagement in connected parts of the global village. Without effective widespread access to ICT, the digital divide further alienates citizens within and among countries of the world and amplifies divides already established ethnic, gender, income, and geographic inequalities. Both government agencies and scholars have studied carefully the digital divide and have suggested creative ways to ensure access to equipment, education, and viable signal connections in order to maximize fuller participation in this dynamic global ICT phenomenon.

A review of literature early on in the rollout of the WWW reveals attentiveness to more than just lack of access to the rich technological resources some enjoyed. In their assessment of the digital divide, scholars highlight that the chasm is much more complex than its original sense involving widespread inequalities on various political, economic, educational, demographic, ability, and gender levels (Alampay, 2006; Barzilai-Nahon, 2006; Colle and Roman, 2001; Dagron, 2001; DiMaggio, Hargittai, and C & S, 2004; Fink and Kenny, 2003; Norris, 2001; Parkinson, 2005; Potter, 2006; Simpson et al, 2004; and Warschauer, 2003). While admitting, for example, the excitement of the Internet’s impact for optimizing

networking in the global village, Norris (2001) raised some critical questions as to whether or not the Internet would evolve into a democratic participatory medium offering equal advantages for engagement or would it only reinforce dominance and inequality. Beyond a binary construction of the digital divide rendering it more complex, Norris describes three divides that called for a response: the global divide that focused on access; the social divide that alienated people; and, the democratic divide that illustrated the use or lack of use of the Internet for political purposes. Van Dijk and Hacker (2003) identify psychological, material, skill, and usage factors that influence this access. Hilbert (2004) focuses on the gender divide while Preiger and Hu (2006) study the racial divide, both further specifications of the digital divide. Kularski and Moller (2012) further specify the digital divide focusing on technological skill gap. The challenge, Kularski and Moller note, involves more than supplying ICT equipment and ensuring access points to digitally excluded people. Users need to be trained how to use technology optimally for their needs.

Castells (2001) highlights the strong relationships between the different geographies of the Internet: technological geography, geography of users and economic geography. Castells affirms that Internet is the technological tool able to distribute the informational power, knowledge and capability to connect people into different networks. To be disconnected means to be marginalized in the global system. For this reason the sentence about the need for the underdeveloped countries to start from the real needs of the third world (health, culture, water and electricity), before thinking to Internet, reveals a deep misunderstanding. Without Internet no Country has the possibility to generate the resources able to satisfy the needs linked to the development. Following Castells (1996) Internet has the control and accessibility to informative flows, although not homogeneously dislocated in the world, configuring new geo-political balances on the basis of new geo-informational maps of the

“Internet Galaxy”. It is a fact, that the relationship between science and both society and media, is profoundly changed. In the last two decades, we have been observing a structural transformation of traditional communicational channels, where tele-communication was used to connect people physically separated from each other, toward a new pattern of “connected presence” (Castells, Fernandez-Ardevol, Qiu & Sey, 2007). In this new model, small gestures or signs of attention may be at least as important as the message content itself.

MAPPING THE DIGITAL DIVIDE

46% of the world population is connected to the Internet, a far cry from 1% in 1995 (Internet Live Stats, 2016). Statistics report considerable growth in digital usage for the past sixteen years (Internet World Stats, 2016). However, evidence also amplifies that the African, Asian, and Middle Eastern regions still lag in Internet connections significantly impacting the larger global digital divide. 2.1 billion of the 3.3 billion Internet users lived in 10 countries (Internet Live Stats). The rest comprised the bottom quarter and among 191 other countries of the world. Heading the list of countries were China, the United States, India, Japan, and Brazil. The most connected countries are Iceland, Faeroe Islands, Norway, Bermuda, Andorra, Denmark, and Liechtenstein all averaging approximately 96% Internet penetration per population rates. The least connected countries of the world are, in ascending order, Eritrea, Timor-Leste, Burundi, Somalia, Guinea, and Niger, all with no more than 2% Internet penetration rates.

A number of different efforts have been made by scholars and journalists to illustrate visually the digital divide. Chris Harrison from the Human Interactions Institute at Carnegie Mellon University tracked Internet access over a four year period. In a 2011 map, Harrison showed the increased user connections throughout the world and, at the same time, demonstrated Internet ac-

cess remained unattainable for areas of the world where access could be transformative for their human condition.

In 2011, Gregor Aisch, a graphics editor at the New York Times, used IP addresses taken from GeoLiteCity database by MaxMind to visualize the global digital divide. He did qualify his findings by noting that his employment of IP addresses did not recognize the widespread use of mobile devices in Africa. Harrison and Aisch capture well in their dark spots of the world the locations and extent of the digital divide.

The digital divide also has garnered attention from leadership in the public and private sector given that the global community has become quickly enriched with technology. As a world increasingly dependent on technology for its rich resources, consistent efforts have been made to analyze and make provisions to resolve the digital divide. Any technological deficit only furthers digital inequalities making it difficult for the least connected countries to compete, participate, resource, and communicate the information superhighway. The World Summit on the Information Society declared that the global challenge for the new millennium is to build a society “where everyone can create, access, utilize and share information and knowledge, enabling individuals, communities and peoples to achieve their full potential in promoting their sustainable development and improving their quality of life” (World Summit).

Since 1995, the United States Department of Commerce’s National Telecommunications and Information Administration’s (NTIA) has studied the issue of ICT diffusion publishing regularly its findings and strategies to resolve the unequal distribution (1998, 1999, 2000, 2002, 2004, 2007, 2009, 2010, 2011, 2013, and 2014). Its 1995 research report “Falling Through the Net: A Survey of the ‘Have Nots’ in Urban and Rural America” is often credited with coining this term “digital divide,” the NTIA report acknowledged the revolution that had begun impacting many Americans positively. Although, the report’s

findings offered a broad perspective on the digital divide, the term “digital divide” itself can be found nowhere in the government document. Earlier in 1994, Steve Case, the then-AOL Chairman and CEO, identified the digital divide in his remarks: “There’s no single solution to bridging the digital divide... We must take steps now so that in the Internet Century, no children are left behind” (Norris, 2000). A more descriptive appreciation of the phrase “digital divide,” however, is known to have more popular origins in print media. In January 1996, New York Times journalist Gary Andrew Poole reported on the digital divide in education between two schools in the center of the technologically rich Silicon Valley (Poole, 1996). One school had access to the latest computers while another proximate one had outdated ones offsetting the array of opportunities the former enjoyed. Later that same year, Los Angeles Times writer Amy Harmon used the term “digital divide” to describe the social distance she felt as a wife felt towards her husband preoccupied with surfing the Web (Harmon, 1996). Despite its novel origin as a social construction in describing a marital exchange, Harmon offered initial insight into how an individual, particularly a woman in this case, and in the overall historical schema of the global digital divide, could be estranged from the obvious engaging resources of the Web. Interest in the digital divide was raised to national prominence in October 1996. In an address to the people of Knoxville, Tennessee, then-President Bill Clinton and then-Vice President Al Gore used the term “digital divide” twice to amplify their concern for those who would be left out of the American dream (Wilson, 2009).

In July 1998, the NTIA published “Falling Through the Net: A Survey of the ‘Haves’ and ‘Have Nots’ in Rural and Urban America” with “Falling Through the Net II: New Data on the Digital Divide.” In July 1999, the NTIA released its third publication “Falling Through the Net: Defining the Digital Divide.” The NTIA published “Falling Through the Net: Toward Digital Inclusion” in 2000 and “A Nation Online: Internet Use

in America” in 2002. Broadband was the focus of the NTIA’s 2004 report “A Nation Online: Entering the Broadband Age.” In 2007, the NTIA published “Networked Nation: Broadband in America” and continued its discussion of broadband service with its 2009 publication of “Digital Nation: 21st Century America’s Progress Towards Universal Broadband Internet Access.” November 2010 saw the release of its document “Exploring the Digital Nation: Home Broadband Internet Adoption in the United States” and in 2011 “Digital Nation - Expanding Internet Usage.” The NTIA’s 2013 publication “Exploring the Digital Nation: America’s Emerging Online Experience” tackled the digital divide by identifying first what Americans do online and its 2014 report “Exploring the Digital Nation: Embracing the Mobile Internet” illustrated the move from personal computers to mobile devices.

In addition to the regular thorough analysis that the United States NTIA has done to highlight the disconnectedness of so many of its citizens since the diffusion of technology to the public, the European Union (EU) also has sought to resolve the challenge of the digital divide. In 2010, the EU published “Europe 2020 Strategy” which has sought “smart, sustainable and inclusive growth for European Economy” so as “to exit the crisis and prepare the EU economic for the challenges of the next decade” (European Commission, 2015). Member nations acknowledged that “in a changing world, we want the EU to become a smart, sustainable and inclusive economy. These three mutually reinforcing priorities should help the EU and the Member States deliver high levels of employment, productivity and social cohesion.”

A “Digital Agenda for Europe” is one Europe 2020 Strategy’s priorities, a “flagship initiative.” The EU recognized that digital engagement through ICTs is critical to growth and sustainability. It could not be a mere bystander as technology transforms the global community. The European Commission earmarked 1 billion Euros to extend digital inclusion to rural areas in the hopes of generating significant economic growth. All 27 member states of the European

Union were charged with evaluating the digital divide specific to their own country and working in concert with other nations to resolve it. Unlike the United States’ NTIA’s regular updated published reports EU created a website <http://ec.europa.eu/digital-agenda/> tailored to offer citizens and officials access to analytics and monitor progress in each EU country.

The digital divide also has been a central concern on the international level. In 2000, the G8 formed the Digital Opportunity Task Force. This task force was a collaborative effort among governments, private sector enterprises, and not for profit organizations to brainstorm strategies as to how to resolve the digital divide and deliver technology to marginalized parts of the world (Hart, 2001). In 2001, the United Nations Information and Communication Technologies Task Force took up the same task and continues its mission to today. This task force disseminates information about the digital divide, builds alliances with corporations and nonprofits, and works closely with people from less connected countries in both connecting them to the Internet and sustaining them in their technological development.

In 2012, UN Secretary General Ban-Ki Moon called for renewed efforts in bridging the digital divide, noting that “All people must be able to make the best use of information and communications technology to help create the future we want” (United Nations News Centre, 2012). Moon’s words build upon the United Nations’ Human Rights Council unanimous resolution to identify internet access and online freedom of expression as a basic human right (Estes, 2011). Yet, this goal remains elusive given the fact that, according to the United Nations’ International Telecommunication Union’s own data, while around one third of the global population was online, almost two thirds of the population was not.

BRIDGING THE DIGITAL DIVIDE

Evident progress has been made to get people online. A number of creative contemporary solu-

tions that have sought to close the digital divide in the global village. This section will highlight only three of the many creative endeavors initiated by strong partnerships between less connected countries, businesses, and human interest organizations.

The One Laptop per Child (OLPC) initiative was founded by Nicholas Negroponte in 2005 in a joint partnership with leading technology corporations. OLPC distributes those familiar white computers and more recently tablets with green antennae. The attraction is its sticker price which at one point in its history was 100 USD. While the project is not without criticism from those suggesting other human matters should be prioritized, evidence indicates that OLPC has reduced digital inequality and promoted education, health, and welfare (Cotten, Hale, Moroney, O'Neal, and Borch, 2011; Selwyn, 2013; and Warschauer, 2012).

The British Council and Microsoft have partnered to upgrade technology in Kenya by creating a “Badiliko,” in kiSwahili, a “digital hub,” for students to gain full and free access to the Internet in over 100 schools. This collaboration also involves the training of teachers. It is a small effort to provide students with online learning resources and connect them with peers and teachers throughout the world considering the magnificent number of students enrolled in education (BBC News, 2013; Gbolagade Adekanmbi and Bopelo Boitshwarelo, 2012).

Another program that seeks to bridge the digital divide is the Close the Gap organization, based out of Brussels, Belgium. In its mission statement, Close the Gap acknowledges that it seeks to “bridge the digital divide by offering high-quality, pre-owned computers donated by European companies to educational, medical and social projects in developing and emerging countries. Unfortunately, laudatory efforts such as these are not always successful in bridging the digital divide for a variety of reasons, including “outdated and underfunded programs, lack of comprehensive solutions, uninspired models of technology in education, and non-holistic ap-

proaches” (Evans, 2010). A history of debt in the global South, too, has precluded unconnected nations from having the infrastructure and capital to sustain hopeful endeavors only pushing the further into a downward spiral of further fiscal distress, disease, and illiteracy. Admittedly, wealthier nations with a surplus of equipment, generally dated and sometimes inoperable, donate technology equipment to poor nations. However though, historically there tends to be little to no follow-up educational tutoring for the digital illiterate; no sustainable strategies to access the Internet given infrastructure and operational barriers; and, no ongoing support for computer repair.

IMPETUS FOR RESOLVING THE DIGITAL DIVIDE

Technology empowers people. The last decade has demonstrated this. In the Occupy Movement in Northern Africa, technology was the key medium to offsetting a history of injustices and tyrannies. The national leadership in Egypt was so threatened by what could be accomplished by technological communication that it shut down access to the Internet for five days. China has done similarly. Access to the Internet “created a world of carnival, community, and contention in and through cyberspace and how in this process they have transformed personhood, society, and politics” as “a response to the grievances, injustices, and anxieties caused by the structural transformation of Chinese society” (Yang, 2009).

Being connected to the Internet has the capacity to revolutionize peoples through access to informational resources and communication platforms, but technology must be accessible in order to harness its power. Unfortunately, for much of the world, particularly those in the southern regions of the globe, the prospect of having a decent computer equipment and a sustainable infrastructure to support broadband access seems as realizable as relief from their persistent impoverishment, hunger, and illiteracy.

Technology is not the panacea to the panorama of problems plaguing the world. Closing the digital divide and affording people Internet access could lead to a lessening of the world's deleterious problems through the Internet's capabilities. Poverty, oppression, hunger, human trafficking, clean water, violence and war, to name some of the more pressing global concerns, may not be able to be fully resolved through digital connectivity, but could be ameliorated by using the Internet as a *catalyst*. Although, not all tech leaders agree with my claim that bridging the digital divide would alleviate many of the problems plaguing developing nations. Bill Gates reminds the global community that technology alone will not solve basic problems inherent to developing nations (Stone, 2013). Yet, access to technology is increasingly becoming an important component to alleviating poverty and increasing opportunities for marginalized populations across the world. However, narrowing the digital divide has the capacity to inform and connect people to previously unavailable resources. Expanding online access levels can level the playing field in the global economy and offer a constellation of advantages for connected individuals.

Technology extends the range of possible outcomes and without an Internet connection, unequal opportunities for economic, political, and social growth persist. The digital divide eclipses the opportunities to access the wealth of resources available on the Web for individuals, communities, and nations for education, collaboration, and significant development.

FUTURE RESEARCH DIRECTIONS

Resolving the digital divide requires a multi-dimensioned response and will continue to entail a great deal of strategic analysis and priority planning. Further research to study carefully many of the critical concerns raised in this chapter will be important to sustain momentum to close

the digital gap. While the penetration of mobile devices throughout the global village has been hailed as a significant advancement in bridging the digital divide, mobile telephony is only a step. A person, using the mobile phone for Internet access in its present form, cannot engage fully the wider resources on the Web; a larger Internet connected computer or tablet is ideal. In addition to securing physical provisions for technologically handicapped nations, access to reliable and economically reasonable Internet signals also are as important.

Another area of future research must involve ongoing training and development. Internet connected computers cannot merely be given to digitally challenged nations with the expectation that they will be able to maximize the use of technology. While the technological learning curve can be thin in younger populations who are more willing to take risks and learn through experimenting with technology, strategic efforts to ensure training and subsequent updating of the wide range of computer users will be critical. As advancements in computer technology become available, it also would be important that work be done regularly to supply the more marginalized and vulnerable communities with contemporary machinery, stronger Internet signals, and updated software. In the latter case, the Open Source Movement offers marginalized peoples opportunities to use common software programs and, at the same time, participate in tweaking the software (Bergquist, Ljungberg, & Rolandsson, 2011).

A final area that researchers need to study more deeply focuses on the motivations on leaders and nations to restrict access to the ICT. It is evident that the plethora of information and connections offered through ICT can maximize global engagement and industrious innovation. At the same time, there are some leaders of nation states that are threatened by the resultant thoughts and actions after interacting with the massive capabilities the Internet offers. Research into how cultures have advanced through their engagement with ICT and

how Luddite countries might move beyond its technological paralysis would be helpful to both individual citizens and the global community.

CONCLUSION

The revolutionary reach of ICT has extended to many parts of the world offering different global communities significant opportunities for growth in economic, educational, political, and social areas. Unfortunately, a goodly number of global citizens do not enjoy having access to technological equipment and being connected to the powerful resources available through this celebrated historical advancement. This reality commonly known as the digital divide further heightens socio-economic disparities by handicapping the potential to connect for information and communication. In a rather unfortunate unfolding of events, the Internet which was intended to connect people and build livelihoods, in some instances, only has isolated people further and deepened already existing inequalities. This chapter examined the digital divide using insights and data from academic and government resources. Both scholars and officials acknowledge that digital divide is closing through specific efforts of organizations and governments. At the same time, both of these constituencies admit much more work has to be done to bridge the digital gap, particularly with only 40% of the world's population connected. An integrated response must involve access, use, skill, language, background and environment. Accessibility to connected technology leads to greater inclusion, resolving digital inequalities often reflective of deeper economic, political, social, educational, and demographic inequities.

KEY TERMS AND DEFINITIONS

Access: The physical proximity to computer technology, electricity, and an Internet signal.

Affordability: The financial means to access or purchase computer equipment, electricity and an Internet connection.

Broadband: Wide bandwidth data transmission using a fixed cable or fiber optics or combination, or through wireless satellite services, to conduct multiple signals.

Connectivity: The vibrancy and speed of an Internet connection often dependent on the Internet service provider (ISP) used.

Digital Divide(s): A multi-dimensional reality where only 40% of the world's population has access to the Internet.

Internet: A computer network that can be accessed through a dial-up modem, digital or cable network like, satellite, or broadband connection.

Marginalization: The relegation or neglect of a specific group of people to the fringes of society.

World Wide Web: The user-friendly platform on which users interact with others and resource information on the Internet.

Eight Tips for the Theme, “Data and Forecasts”

Alessio Drivet

GeoGebra Institute of Torino, Italy

INTRODUCTION

Paul was a common octopus living (January 2008, October 2010) in a public aquarium at the marine life center in Oberhausen, Germany. Paul experienced some international notoriety during the 2010 World Cup when it was used to “predict” the results of football matches in which the German national football team was involved and the final (that was not played by Germany). Paul’s predictions were all correct.

The octopus belongs to Octopodidae family and has eight tentacles, therefore we imagine that each of these gives us an indication as to which are the best strategies to analyze resources and obstacles of teaching probability and statistics.

Mathematical artifacts shown in the figures are the basis of a project that could be called educational gaming. The collection of materials found, purchased, and constructed is the result of many years of research work (Drivet, 2013). They are taken from <https://sites.google.com/site/oggettimatematici/home> site. Currently there are 210 objects and, of these, 40 relate to the mentioned subject (Figure 1).

BACKGROUND

Numbers, geometry, relations and functions, data and forecasts are the four themes that characterize the classic division that has gradually made its way (albeit with some linguistic difference) within the Programme for International Student Assessment (PISA), the TIMSS (Trends in International Mathematics and Science Study) and,

with regard to Italy, the UMI (Italian Mathematical Union), the INVALSI (National institute for the evaluation of the education and training system) and the National Guidelines for the curriculum.

This text will tackle issues related to data and forecast, only partially similar to the traditional concepts of probability and statistics.

A first starting point is provided by this quote: “Probability is the theory which organizes the world of chance phenomena. One has to start with phenomena which beg to be organized: intuition about unpredictable events, games of chance, occurrences which seem to happen without regularity etc. One then has to teach the learner to constitute the mental object for himself/herself. This is the stage preceding concept attainment but too often ignored” (Kapadia & Borovcnik, 2012).

As a matter of fact, there is a difference between the theory of probability and the theme of the data and forecasts. The task of data and forecasts means analyzing and interpreting data, developing conclusions and reasoning also with the aid of graphic representations, consciously using the calculation tools and the potential offered by IT applications.

EIGHT TIPS

First Idea: The Different Registers

The following quote makes it perfectly clear the key concept.

“For example, if you throw an ideal dice cube and one wonders what is the probability of getting either 1 or 6, it can be answered in different ways,

DOI: 10.4018/978-1-5225-2255-3.ch402

sets (such as lists of patients' pulse rates or baseball players' batting averages)"(Pfenning, 1998).

Figure 2. Dice

Table 1. Register and Representations

Registers	Representations
Linguistic	2 of 6
Fractional	1/3
Decimal	0.33
Percentage	33.3%

Second Idea: The Role of Combinatorics

One question: the introduction of combinatory calculus in school teaching has a mathematical autonomous value or is it a simply tool in order to teach probability?

The discussion would take us away; here we examine only the utilitarian aspect underlining the fundamental principle of the calculation, namely the principle of multiplication.

A typical example is the slot machine and the definition of the number of possible winning combinations. The ideal would be to have a concrete object (Figure 3).

The goal is to be able to achieve a winning combination between the figures that appear on the reels. To play, simply pull the arm that controls the reels of slot machines, wait until they stop, and see if the output is a winning combination or not.

The odds of winning vary according to the type of slot.

Taking a cue from the slot machine in the picture we can see that there are three reels and five symbols: BAR, cherries, apple, 7, \$.

Lowering the arm, the wheels move independently to form an arrangement among the 5^3 possible.

You win if you get a triple BAR or a triple 7, or two BAR and a 7 or two 7 and a BAR.

In total you have eight winning combinations.

The probability of winning is therefore equal to $8/125 = 0.064$.

In other words: if you play 1 \$, in case of victory, you should get $0,064 \cdot S = 1$, i.e. 15.63 \$.

In practice, the pay-out will be much lower, and “You will play at a loss.” You have to know

Figure 3. Slot machine

that in Italy for every euro introduced in slot machines a portion of that money is transferred to the Treasury and to the managers. Tobacco shops or coffee shops machines distribute only 75 percent of the collected amount!

The basic idea (in teaching) is that the items should be introduced, first, by an intuitive point of view, using a variety of examples and, only later, by mathematical formalization.

Third Idea: Coins and Dice in Various Probabilistic Approaches

All the textbooks use examples referring to coins, dice, cards, marbles, etc. The reason is known: you can build simple examples that will (should?) leave room for more complex random situations.

This approach can be improved by expanding the range of “coins” and “dice” used to make a transition logically motivated by the classical definition to the frequentist probability. As examples

(Drivet, 2013), we cite thumbtacks (Figure 4) or astragals (Figure 5).

The thumbtacks have two possible ways to fall and therefore could be treated like a coin with two faces. A thumbtack can drop with the tip downwards or upwards, but in this case you cannot apply the probability in the classical sense, because the two events do not have the same probability just because of the geometrical structure of the object.

In order to provide an assessment of probability (for example the exit of the tip up which we will call Head) the thumbtack should be launched a sufficiently high number of times in order to get a valuation given by the ratio between favorable outcomes and attempts.

Since there are different types of thumbtacks you can direct students to get them to justify an argumentation on the probability of the event “head”.

Figure 4. Thumbtacks

Figure 5. Astragal

Astragal (Talus or Anklebone) is one of the group of foot bones known as the tarsus. It has particularly regular proportions and, since ancient times, taken from goat and mutton, it was like a sort of with 4-sided dice. Of course it is not a fair dice.

Also in this case the objective is to compare the results of a regular dice with those of the talus.

A small digression: Astragal was used in games of chance, but also to predict the future. In Iceland it was (and it is) used to have an answer to a question. First it is read the following magic sentences that, in English, more or less sounds like this: “Tell me, my Vala, the answer to my question. I shall gladden you with gold, and satisfy you with silver if you tell me the truth. But I shall drown you in urine and burn you in fire if you lie to me”.

Then astragal is launched and if the bone falls with the convex face upwards the answer will be positive, if it shows the concave surface the answer is no, otherwise there is no certain answer.

Fourth Idea: Information Technology

Computer software offers the opportunity for students to learn about modelling. It enables students to build their own models in order to describe data and to generate simulations that can be explored.

“Computer-based assessment gives students the opportunity to work with larger data sets and provides the computational power and data handling capacities they need to work with longer

available sets. Students are given the opportunity to choose appropriate tools to manipulate, analyze, and represent data, and to sample from data populations. “(PISA, 2012).

In class, we work too often with invented data. Often the presented data are not real and not even realistic. Sometimes they fit so close to the model then they seem completely artificial. (Gattuso, 2011).

It will be up to the teacher, based on the age of the students of available resources and skills, to decide whether to use a spreadsheet as Excel (Salkind, 2016) or Calc, Geogebra (Prodromou, 2014). R (Ferreira, Kataoka, & Karrer, 2014) or online available tools such as Core Math Tools (Hirsch, Keller, Fonger & Edson, 2013).

An area that presents an interesting development possibility is the statistical packages that allow you to manipulate, summarize, and analyze data using statistical techniques and methods. Particularly interesting is the evolution of the Apps for Mobile Device (Edwards, 2015).

Fifth Idea: Small and Big Data

A question arises; in the school, it makes sense to do statistics with a few data? A clear answer does not exist, but it is clear that confine itself to processing only a few components (“guys, calculate the arithmetic mean of these five numbers”) is limited and often misleading.

There not here the place to deepen the important problem of the so-called big data. Nevertheless, is certainly useful to work with a data set sufficiently wide to provide materials for not trivial considerations and inferences.

Let us clarify this aspect. In the school it is unthinkable to work on large data sets (often not available) that would require not only appropriate software, but also a different approach. Martin Lindstrom (2016) says: “Big Data is all about finding correlations, but Small Data is all about finding the causation”.

The balance should be a dataset sufficiently significant but easy to handle.

For many problems and questions, small data are enough. Everything processed in Excel is small data.

Anthropometric data of sufficient amplitude are therefore strongly recommended. For example, in Italy, you can use the data collected from CIRDIS (<http://cirdis.stat.unipg.it/index.php?canale=160&lang=ita>).

Another suggestion (Frictionless Data) can be found at <http://data.okfn.org/> where a small set of lightweight data package provide a base structure on which tooling and integration can build.

Sixth Idea: The Probability is Not Just a Game

It is true that the birth of the first probabilistic concepts is closely linked to games of chance, but it would be wrong to introduce students only to this aspect. Without pretending to go into detail it is necessary to present a number of areas in which you can use stochastic models, for example: environmental (weather forecast), economic (predictive models), medical (diagnostic), social (insurance).

It is desirable the use of artefacts, spreadsheet and Web resources such as mortality tables.

Weather Forecast

A rain gauge (Figure 6) is an instrument used by meteorologists to gather and measure the amount of liquid precipitation over a set period of time.

Analysis of weather conditions is an ideal tool to introduce statistical and probabilistic concepts. The theme is very timely, given the general level of interest shown by the population.

Predictive Models

The Big Mac (Figure 7) index was invented by The Economist in 1986 as a light-hearted guide to whether currencies are at their “correct” level. It is based on the theory of purchasing-power parity (PPP), the notion that in the long run exchange

Figure 6. Rain gauge

rates should move towards the rate that would equalize the prices of an identical basket of goods and services (in this case, a burger) in any of the two countries whose currencies are compared.

The Big Mac PPP exchange rate between two countries is obtained by dividing the price of a Big Mac in one country (in its currency) by the price of a Big Mac in another country (in its currency). This value is then compared with the actual exchange rate.

Figure 7. Big Mac

Diagnostic

An ultrasound examination can provide a starting point for a statistical survey (Gross, Callen, Filly, 1982).

By indicating with BPD the bi-parietal diameter and with OFD the occipital-frontal diameter (Figure 8) the problem can be formulated as follows: “From these ultrasound data, which is the formula that can more accurately estimate the head circumference (CC) admitted that the machine being used is not sufficient to measure it?” (Drivet, 2006)

In addition to reasoning of geometric type, the solution of the problem also involves references of statistical type.

In the literature we can find numerous formulas to be compared with the empirical data.

1. $(BPD + OFD) / 2 * 3.14$
2. $\sqrt{((BPD^2 + OFD^2) / 2)} * 3.14$
3. $\sqrt{(BPD * OFD)} * 3.14$
4. $(3 * (BPD / OFD + 2/2) - \sqrt{((BPD / OFD * 2 + 3/2) * (3 * BPD / OFD + 2/2))}) * 3.14$
5. $BPD * OFD + 3 + 1.57 *$
6. $(BPD + OFD) * 1.62$

Figure 8. Echography

The comparison between the different formulas and the estimate of the circumference obtained by the method of least squares, from $z = ax + by$ model, allows students to compete not with the more or less realistic usual problem, but with a sufficiently wide and challenging case study.

Insurance

A life table is a concise way of showing the probabilities of living or dying for a member of a particular population at a particular age.

The table is used by actuaries, demographers etc. to present the mortality experience of a population. This method is applicable to the analysis of many measurable processes and mainly in the insurance field. For detailed analysis, see Namboodiri & Suchindran (2013).

From the tables it is possible to obtain information to answer questions like: what is the probability that a woman aged 20 years will survive fifty years? What is the average number of years of life remaining for men who have just reached their 40th birthday?

The idea that the probability is not calculated as the ratio between the number of heads and coin flips, but as the ratio of survivors of a cohort, is always amazing (Figure 9).

Seventh Idea: The Dynamic Statistic

“Many teachers firmly believe that most students hate statistics, perceive it to be a necessary but painful class to teach, and imagine that it will naturally result in poor course evaluations. Unfortunately, these myths can become self-fulfilling prophecies”. (Hulsizer-Woolf, 2009).

This assertion is perhaps deliberately extreme. It is not actually true that students have a difficult relationship with the statistic. They simply are faced to a not credible simulacrum.

Construction of surveys, research, and creation graphics are essential, but a real quantum leap you can get giving dynamism and historical meaning to the statistics. A good practice is to make use of resources such as the Interactive maps, for example: IMFDATAMAPPER, MAPPINWORLDS or GAPMINDER (Figure 10).

Gapminder Foundation is a non-profit venture registered in Stockholm, Sweden, that promotes the use and understanding of statistics and other information about social, economic and environmental development at local, national and global levels.

Eighth Idea: Modelling

“Modelling is an essential process and the introduction of basic probabilistic notions raises specific issues [...]. Students meet a new difficulty when they have to link probabilistic notions to reality” (Batanero, Burrill, Reading, 2011).

The approach to patterns associated with random events is perhaps the culmination of an educational path. It allows you to switch from probability to statistics in a concrete and meaningful mode. This is one of the cornerstones of the argument: under very general conditions the simultaneous action of a large number of random factors leads to a substantially predictable effect.

“Only with a large number of single events randomness is lost and you fall under the control of statistical laws”. (Eigen & Winkler, 1986).

An excellent example of modelling is due to the above mentioned authors.

Figure 10. Gapminder

To simulate the trend of a population you imagine a game in which black and white pawns are the elements of a population. A chessboard 6x6 is the space where you play the various processes. Two players have randomly put their pieces on the board so that each occupies half of the available squares (Figure 11). Then we introduce the rules of the game that will lead to very different asymptotic probability distributions.

- “Drifting” You flip a coin. If the result is heads, white removes a black pawn and replaces it with a white from its reserves. Otherwise, a white pawn is replaced with a black one.
- “Balance” You roll two dice: the checker from the box corresponding to the coordinates resulting from the shooting is removed and replaced with a spare pawn of the opponent.
- “All or nothing” You roll two dice: the checker from the box corresponding to the coordinates resulting from the roll is doubled at the expense of color opponent. Therefore, if you have obtained a square with a white pawn removes any black pawn and replace it with another white from the reserve.

In the presented cases the asymptotic probability will lead, respectively, to uniform distribution, Gaussian curve, two possible singularities (all or nothing).

Issues

“Probability does not exist” (De Finetti, 1974).

The paradoxical statement, means that the probability is not an immanent property, but a feature of our reasoning about the world.

In this sense, the previous statement opens a window on the subjective probability that is too often neglected in school while would be useful as a first step towards the exercise of critical thinking and a start to the practice of argumentation.

Just one example: how trustworthy are the predictions of bookmakers regarding football?

We have to collect the data on the concordance between prediction (considering winning the team with the lowest quotation) and result to draw conclusions. Merely by way of curiosity, in Italy the percentage, calculated on the last two championships, is equal to 50%!

Figure 11. The chessboard as model

Controversies

“Probability is increasingly taking part in the school mathematics curriculum; yet most teachers have little experience with probability and share with their students a variety of probabilistic misconceptions. Probability is difficult to teach for various reasons, including disparity between intuition and conceptual development even as regards apparently elementary concepts. Since an education that only focuses on technical skills is unlikely to help teachers overcome their erroneous beliefs, it is important to find new ways to teach probability to them, while at the same time bridging their content knowledge and their pedagogical content knowledge” (Batanero et al., 2005).

The raised issues, which will be taken up to the conclusions, are particularly interesting. To these we could add another level of discussion, the contrast between teaching for problems and teaching for patterns. According Carla Rossi (1994) the most appropriate path for teaching probability and statistics should be inductive and follow the scheme:

significant problem → resolving model → results (forecast) → comparison with data → possible modification of the previous model

Problems

Brousseau (1983) describes very clearly some pedagogical obstacles.

Knowledge can be a source of distortions in the sense that the student uses this knowledge to produce the correct answer in a given and known context. When this knowledge is used out of context, it generates errors. The student ignores the contradictions produced by the obstacle and resists to establishing a deeper knowledge.

“Moreover, errors and difficulties do not arise in a random, unpredictable way. Frequently it is possible to discover regularities in them, to find some association with other variables of the

proposed tasks, of the subjects, or of the present and past circumstances” (Batanero et al., 1994).

Working with objects, doing research, making deductions, involves commitment and effort. We must never forget that students tend to apply the criteria of applied mathematics: profit maximization and cost minimization.

Trying to identify objects and situations that speak of a “different Mathematics”, actually embodied in everyday life, could provide more opportunity to treat the innumeracy that seems to afflict much of our society.

FUTURE RESEARCH DIRECTIONS

For the understanding of probabilistic thinking we must to emphasize two aspects. The first concerns the concept of intuitive knowledge as adaptation to the surrounding environment shaped by experience. The second aspect shows that probabilistic intuition differs from the intuition that one has in other mathematical and scientific areas.

Especially in the latter case it is important to find the links between probability and the world around us, with all its objects but also moods or abstract concepts. In this sense, it is crucial to start from significant problems and artifacts to build a solid framework.

SOLUTIONS AND RECOMMENDATIONS

“However, it is also crucial to connect the introduction of probability with the statistical aspects that are involved in everyday life. Students are quite often unable to appropriately take statistical information into account to evaluate probabilities. On the other hand, it is quite remarkable that teachers lack specific knowledge in this field” (Garuti, Orlandoni & Ricci, 2008).

More than solutions it is appropriate to give ideas to those teachers who want to use, at least

in part, this approach. The recommendation is to sparingly use the objects, over a school year, choosing from those which can be situated in a curriculum. For example, you may decide to develop a theme such as the probability by using a dozen objects with a path that, starting from the simplest objects (dice, cards, coins) can get to touch more complex issues such as the binomial distribution (Quincunx or Galton box).

CONCLUSION

We can make some assumptions about why, in school, probability and statistic are, at all levels, as Cinderella. We can single out some aspects of the problem:

- 1. Lack of specific training of teachers in the context Data and Forecasts. Without wishing to generalize it is normal to meet many teachers (or aspiring) who claim to have a very poor university education in this area;
- 2. More limited experimentation and educational research than other nuclei, although

there are praiseworthy local or national initiatives;

- 3. Reluctance to broaden the discourse over repetitive examples of textbooks when the tools of probability and statistics can refer to a very wide range of possible fields of application. For example:
 - a. Environmental: weather forecast, earthquake risk map
 - b. Biological: genetic
 - c. Economic: insurance, forecasting models
 - d. Physical: statistical mechanics
 - e. Legal: evidence assessment
 - f. IT: big data processing
 - g. Language: comparison to award author styles, encryption
 - h. Fun: games of chance
 - i. Medical: diagnostic, screening, spreading epidemics
 - j. Social: data mining, queue management, transport organization
 - k. Technology: quality control, stochastic communication networks

Figure 12. The dials of the probability

4. Limited use of IT tools, not just those complexes although free as R or KNIME, but especially instruments with a favorable learning curve as Excel. It takes only several lines of instruction to turn a spreadsheet into a powerful simulation tool;
5. Excessive use of examples and abstract formulations with exclusive reference to the algebraic language. Here the examples can be multiplied: from combinatorial formulas to Bayes Theorem is a continuous run to remove the student from the discipline pleasure. A reflection should refer to the analysis of simple and deep problems (Figure 12).

Anyway, we must not forget that: “This branch of mathematics is the only one, I believe, in which good writers frequently get results which are entirely erroneous” (Pierce, 1982).

KEY TERMS AND DEFINITIONS

Artifacts: Sometimes indicates an object in a digital environment.

Big Data: A term for data sets that are so large or complex that traditional data processing applications are inadequate.

Combinatorics: A branch of math concerning the study of finite or countable discrete structures.

Dynamic Statistic: The use of dynamic graphics for the representation of statistical data.

Information Technology: The use of a device to store, retrieve, transmit and manipulate data.

Predictive Modelling: Use of statistics to predict outcomes.

Probability: A number between 0 and 1 that measure the likelihood of an event.

Statistic: Discipline that has as its goal the study of quantity and quality of a phenomenon.

Stochastic Modelling: A model that depends on random variables.

Exploring New Handwriting Parameters for Writer Identification

INTRODUCTION

In the XIX century, Giovanni Morelli -Verona, February 25th 1816 – Milán, February 28th 1891- introduced a paradigmatic change in the detection of forgery of famous paintings (Ginzburg & Davin, 1980). Before him, famous picture authentication was based on global indicators such as general illumination, perspective, body position, smiles, and gaze direction, among others. However, such well known characteristics are easy to imitate.

On the contrary, Giovanni Morelli believed that forgeries should be detected watching minor details, such as those less influenced by the pictorial school to which the artist belonged. Every artist automatically produces, almost unconsciously, some details such as nails, fingers, toes, earlobes. These details were considered by Morelli as notoriously revealing, since they appear when the artist's control relaxes and individual impulse take control of his or her actions. Following his conceptual model, Morelli created a large catalog of the minor details of many artists such as Boticelli, Leonardo, Rafael and others. Obviously, trained observers were needed to apply the comparisons advocated by Morelli.

Morelli's method has had a cultural influence over many fields where the search for identifying details began. This change of paradigm led to the use of smaller details in many fields such as people identification. Later, the necessity for better people identification techniques increased. In 1879, Alphonse Bertillon (1893) created an

anthropometric method based on many physical measurements. A few years later, Francis Galton proposed a simpler identification method based on fingerprints. This miniaturization process reached a possible end when started the use of DNA for people identification.

In the specific field of handwriting recognition domain, the evolution followed the same pattern, since old practices, based on global characteristics, such as geometric observable information was replaced by new practices based in parameters which are the result of measurements of smaller characteristics. This chapter proposes some new smaller characteristics, barely observable even by zooming of captured images of the manuscript text.

The automatic processing of handwriting samples is part of the computational biometric. It applies qualitative and quantitative techniques by means of capturing, visualizing and analyzing handwriting. The main applications are writer identification and text understanding. Two significantly different situations appear: on line and off line data capturing. In the former the samples are obtained in a dedicated framework, where the writing instrument and the surface have several sensors. In the latter, the unique information available comes from the residues left on the paper. This chapter deals with the second situation. Width, gray value, direction and other parameters of the residual manuscript text were influenced by the psychomotor characteristics of the writer. Some of these personal parameters may be estimated from the observable properties of the written text.

Any automatic or semi-automatic handwriting recognition process is always composed by at least two activities: i) recognition parameters calculation and ii) comparison of sample parameters with a data bank of registered parameters. Parameter calculation and parameter comparison are quasi independent activities, since almost every parameter set may be used by almost every comparison technique. Very infrequently a better efficiency and efficacy may be obtained by combining certain parameters sets with a given comparison technique. This chapter proposes some new parameters and enhances the understanding of some already in use parameters, leaving the choice of the comparison technique to later studies. The authors believe that the major contribution of the research whose results are presented in this chapter is the better comprehension of the mechanism that creates the residues left on the paper, since some unproven and largely used hypothesis are criticized in some degree.

BACKGROUND

The information recovered off-line from the static residues left on the paper is called pseudo-dynamic. It is clearly different from the actual dynamic information captured on-line during the writing activity. There are many contributions proposing different pseudo-dynamic characteristics, most of them oriented to signature authentication, which is a sub-problem of identification of the author of free text. Some of them are summarized in the next paragraphs.

The work of Ammar et al. (1986) the histogram of the gray level of the signature is analyzed and a pressure threshold is proposed. The signature is described in terms of the percentage of pixels whose gray value that exceeds such threshold, along with other parameters such as the minimum and maximum gray value and the dynamic range of the signature image. Those parameters are compared with a set of signature parameters using classifiers based in Euclidian distance.

A combination of geometric and pseudo-dynamic parameters is used in Huang and Yan (1997). It is based on strokes geometric parameters such as contour, skeleton and the high pressure regions; these parameters feed a classifier based on neural networks.

The proposal introduced in (Fang, 1999), is oriented to geometry; it places the focus on strokes whose size exceeds a length threshold. A softness index is calculated for every one of these strokes. The quotient between the number of soft strokes and the total number of strokes becomes an identification parameter.

A strategy based on pseudo-dynamic characteristics is described in Mitra et al. (2005). It is oriented to the detection of elaborated forgeries. The pressure applied by the writing instrument, estimated by using the gray level of the image, is considered the most relevant parameter. The strategy chooses low pressure pixels as identification parameters. No information about the paper used, the writing instrument or the base where the paper was resting is given.

Another proposal oriented to geometric parameters can be found in Oliveira et al. (2005). It is biased to recognition or authentication of signatures, since it uses parameters not available on free text. Several new geometric parameters are introduced such as the quotient between high and wide, a softness index and inclination in relation with a baseline, among others. Using a similar set of geometric parameters, Lv et al. (2005) propose a Chinese signature verification method. In addition to geometric parameters they include two pseudo-dynamic characteristics: the pixel gray level distribution and the wide of the line. Both parameters are supposed to indicate the pressure applied during the writing process. No indication about the paper, the writing instrument or the base used is given.

In two consecutive articles Vargas et al. (2008, 2011) propose two methods for signature authentication or recognition. Both are biased to signatures. In the first article, the geometric center of the signature is calculated and a polar geometric

system is established on it. An image depicting the distribution of high pressure pixels, contained in polar sectors, is created. The polar sectors are defined by angle and radius limits. This image is binarized using a threshold which is calculated using the gray level histogram of this image. In the second article, the pixel gray level distribution is analyzed using the wavelet transform and the patterns of this distribution is determined by means of the co-occurrence matrix.

In an article oriented to paleographic authors recognition the relation of wide of the stroke and the direction of the trace is analyzed (Brink, Smit, Bulacu, & Schomaker, 2012). The importance of this relationship for author identification is highlighted. In paleographic text this relationship is described in terms of the writing instrument used which was a capillarity-based liquid ink pen. These conclusions are extended to modern handwritings texts. In this case the causes of such influence are attributed to the increasing of the force applied by the stroke authors when the line is going in certain directions. Individual variations are supposed to be partially deliberated and partially unconscious.

NEW PARAMETERS

When dealing with pseudo-dynamic parameter, practically all authors use pixel gray level, its distribution along the stroke, its histogram or other view. Implicitly or explicitly this attribute is referred as the *pressure* applied by the writing instrument on the paper (Ammar, Yoshida, & Fukumura, 1986; Fang et al., 1999; Lv, Wang, Wang, & Zhuo, 2005; Mitra, Banerjee & Ardil, 2005; Oliveira, Justino, Freitas, & Sabourin, 2005; Plamondon, & Srihari, 2000; Vargas, Ferrer, Travieso, & Alonso, 2008, 2011). Even more than that, many times the gray level attribute is directly mentioned as *high pressure* pixels or *low pressure* pixels. In a few articles the parameter *wide of the line* is also attributed to the *pressure* applied (Lv et al., 2005). In the consulted publications, those cited and many others, no indication about the

paper used, the writing instrument or the base used is given. Moreover, neither it was found an article proving the relation between the *pressure* and the gray level nor a citation to such sort of experience. This lack of data motivated the authors of this chapter to do some experiments on that matter. The link between pressure and gray value seemed to be so evident that there was no intention to refute or falsify such relationship (Popper, 1963). The purpose was just to know more about it: to see if it is or not a linear relationship or if it has any peculiarity that may help to understand more clearly the residues left on the paper or surface over which the writing process takes place.

Strictly the use of the word *pressure* in this context is ambiguous since it is not clear if either it is used with the common meaning of the *exertion of force upon a surface by an object* or the more precise semantic taken from physics science as the *force per unit area* (Merriam-Webster Inc., 2004). In what follow, the word *pressure* is replaced by the word *force*.

Vertical Strokes

A very basic experimental array was set up using the followings elements:

- *A writing instrument.*
- *A set of small spheres* of controlled mass.
- *A tube* able to hold the writing instrument and the spheres.

The friction between the tube and the spheres or the writing instrument was ensured to be irrelevant. Inserting the writing instrument in the tube and the some of the spheres on top of it allowed having the possibility of creating strokes, applying controlled forces. At this time the tube and the writing instrument were applied perpendicularly over the paper.

This experimental array may vary upon the use of different writing instruments, different quality of papers and upon the number of sheets. In an exploratory experience like this one, there was no

intention of covering all possible combinations of such factors. For that reason, only one few combinations were used. Changes in the ink color were done, since this factor which was perceived at that time, as being the most important one.

Cross Section and Gray Level

Every stroke was digitalized in such a way that ensures a perfect horizontal image. Figure 1 shows the gray level of pixels belonging to a vertical line crossing the stroke. The gray level of the pixels located before and after the peak represents the gray value g_p , of the unwritten portion of the sheet. For each pixel of the skeleton, the gray level of the darkest pixel on such vertical segment g_d is chosen. The medium gray level of all pixels chosen is taken as the gray level of the stroke; and it is shown in the Figure 2a. To calculate a wide of the stroke, for each pixel of the skeleton a reference gray level g_r is calculated as:

$$g_r = (g_d + g_p) / 2$$

The cross section is defined here as the number of pixel of the vertical segment whose gray value coincides or is darker than g_r . Strictly, the cross section is the wide of the stroke having at least a given gray level. The medium of such cross section wide along the whole stroke is presented in Figure 2b, as a function of the force applied.

Using different spheres, straight strokes under forces from 10 grams -force to 150 grams-force were obtained. Figure 2a presents the influence of the force applied on the cross section wide of the stroke. Figure 2b depicts the relationship of the gray level of the stroke with the force applied. The influence of the force applied on the gray level is almost linear when the applied force varies between 0 and 50 grams-force. If stronger forces are applied the gray level changes very little. For the cross section, the influence of the force keeps its linearity up to 150 grams-force.

Inclined Strokes

Concurrently with the controlled strokes with specific forces, direction and position of the writing instrument, samples of totally uncontrolled free writings were taken, using the same writing instrument, same paper and same number of sheets. The observation of the gestural actions of the writers and the residues left on the sheet of paper, lead to propose a new hypothesis linking the cross section and gray level with the position of the writing instrument.

The experimental array was slightly modified by cutting the tube in a predefined angle. This forces the writing instrument to have a non vertical contact with the sheet of paper. The position of the writing instrument may be in any position in relation with the direction of the stroke. To

Figure 1. Gray value along a line vertical to the trace

Figure 2. (a) Gray level of darker pixels for different forces. (b) Cross section of the stroke for different forces

reduce the number of samples, three archetypical positions were used:

- **Inclined Against the Stroke:** The projection of the position of the writing instrument coincides with the fragment of the stroke already created.
- **Inclined Forward the Stroke:** The projection of the position of the writing instrument coincides with the fragment of the stroke not created yet.
- **Inclined Perpendicularly to the Stroke:** The projection of the position of the writing instrument falls at a right angle with the stroke.

Using different tubes, inclined strokes samples were obtained for 30 and 45 degrees angles between the writing instruments and the vertical. For angles forward the stroke, the whole stroke looks lighter than the vertical one with similar force. On the other hand when the angle is against the stroke, its gray value is very similar to the vertical one. These results may be observed with just a few samples. Perhaps, controlled experiences involving more samples will distinguish vertical and

inclined against the stroke gray values. It should be noted, that the experimental array was based on the mass of a reduced set of small spheres. Table 1 depicts the average gray value of inclined and vertical strokes under two different forces.

Additionally, samples obtained for strokes when the inclination is perpendicular to the stroke show darkness very similar to those obtained with vertical strokes with similar forces. However, these samples show an important new characteristic: the gray distribution on the wide of the trace is notoriously asymmetric. The darkest pixel on a line perpendicular to the stroke appears away from the skeleton. This is rather different from what is shown in Figure 1 where the darkest point and the skeleton coincide or they are close to each other. When the inclination increases, both the asymmetry and the distance between the skeleton and the darkest pixel also increase. Table 2 contains some data related to the distance between the skeleton and the darkest point.

The asymmetry of the gray level across the stroke may also be visualized comparing the average gray value on the pixels on both sides of the skeleton. Table 3 contains come data on that matter.

Figure 3. Experimental array

Table 1. Gray level of vertical and inclined stroke under different forces

Force in gf.	Vertical	45° Inclined Against the Stroke
75	169,33	187,53
90	141,87	157,52

Table 2. Distance, in number of pixels from the darkest pixel and the skeleton

Sample	30° Angle	45° Angle
1	20,99	28,29
2	24,45	29,68
3	22,29	28,48
4	26,99	30,04

SOLUTIONS AND RECOMMENDATIONS

Just with the data collected on this preliminary experiment, it is possible refute the widely accepted assumption that the gray level of the stroke is an indication of the force applied by the writer. Actually the gray level of the pixels depends, at least, upon two factors: the force applied and the inclination of the writing instrument.

On handwritings free of restrictions most of the strokes are curves. On this curves the distance between the darkest pixel and the skeleton varies along stroke. The perpendicular to the tangent to the skeleton of the curve at the position where the asymmetry reaches a maximum provides a mean to estimate of the direction at which the writing instrument is pointing. The distance between the darkest pixel and the skeleton is an indication of

Table 3. Average and median of the gray value of pixels on both sides of the skeleton

		1	2	3	4	5
Right Half	Average	180,57	166,75	165,63	169,40	165,30
	Median	180,57	173,78	168,63	175,00	166
Left Half	Average	202,34	189,55	190,25	187,70	176,47
	Median	202,35	190,41	190,26	189,41	176

the angle at which the writing instrument was hold. Other significant pixels of the stroke are those where the line created by the darkest pixels coincides with the skeleton. In these points the tangent to the skeleton is another indication of the inclination of the writing instrument.

FUTURE RESEARCH DIRECTIONS

All results presented in this chapter are qualitative since they only established the importance of the studied parameters. No quantitative relationships among observed residues left on the paper and dynamic gestures of the writer, were obtained.

Two main line of research may clearly be pointed out at this time:

- **Determine the Influence of:**
 - The type of paper.
 - The surface where the paper is resting.
 - The type of writing instrument.
- **Include These New Parameters in Classifiers:** To determine their contribution to improve the identification of the writers.

CONCLUSION

This chapter deals with approaches for extracting characteristics from handwriting text. These approaches are non invasive and of low cost. They are of low cost because they only need an image of the text. They are non invasive, since the original text is not modified in any way. Additionally, they allow multiple analyses. They are focused on the small deformation produced on the paper and the distribution of the gray level in every section of the strokes.

Results obtained coincide with already published results Ammar et al. (1986), Mitra et al. (2005), and Vargas et al. (2008) in the sense that the gray value and the cross section [Lv2005] are highly repetitive for strokes of the same grapheme created by the same author. These results were

extended from the point of view of the mechanisms that influence both the grey value and the cross section of the stroke. The implicit hypothesis that only the force applied is the driving cause was refuted since both values are also influenced by the relationship between the inclination of the writing instrument and direction of the movement.

It is also determined that it is more revealing to use the evolution of the gray level along the stroke than the use of histograms (Ammar et al., 1986; Mitra et al., 2005; Vargas et al., 2008). Histograms hide very valuable information such as the distance between the darkest points of the stroke and the skeleton. When this distance is:

- **Near to Zero:** The tangent to the stroke is an indication of the position of the writing instrument.
- **Maximum:** The perpendicular to the tangent is an indication of the position of the writing instrument.

Finally, the distance between the line of the darkest pixels and the skeleton suggest the inclination of the writing instrument.

KEY TERMS AND DEFINITIONS

Authentication: The acceptance or the rejection of the identity given by a person.

Biometric Systems: Assemble of equipments, hardware and software whose purpose is to authenticate or identify persons automatically. They are based on the capture of several biometric parameters and the comparison of them with the same set of parameters already known of identified persons.

Biometry: The science that procures to obtain numeric value from biological phenomena and the use of such data in the automatic identification or authentication of human beings.

Co-Occurrence Matrix: A statistical matrix use for measuring texture in images. Could be considered an image by itself.

Graphology: It is a pseudoscience that claims its ability to identify the writer, indicate his or her psychological state at the time of writing, or evaluate his or her personality by means of the analysis of the physical characteristics and patterns

of handwriting. The term is sometimes incorrectly used to refer to forensic document examination.

Identification: The determination of the identity of a person, by a biometric system.

Off-Line: Acquisition of biometric parameter from the residues left by the human being actions. In handwriting analysis these residues are: the gray level and the wide of the strokes including the form of the stroke.

On-Line: Acquisition of biometric parameters in real time. In handwriting analysis, the writing instrument, the surface or both have sensors capturing position, trajectory, force and inclination.

Pseudo-Dynamics Characteristics: Parameters acquired off-line used as estimators for on-line data.

Questioned Document Examination: Forensic phrase used to refer documents that are potentially disputed in a court of law. The primary purpose is to provide evidence about a suspicious or questionable document. Evidence might include alterations, chain of possession, damage, forgery, origin and authenticity, among aspects.

Haptics–Based Systems Characteristics, Classification, and Applications

INTRODUCTION

With advances in technology, individuals today can interact with computer technology, not only through their visual and auditory senses, but also through touch. The sense of touch is unlike other senses such as vision and hearing; its uniqueness lies in the fact that it enables a bi-directional exchange of information between users and the virtual or real environment, whereas the other senses, such as sight and hearing, are uni-directional forms of interaction, taking place from the computer application to the user.

A haptics-based system utilizes the tactile sense of touch, the kinesthetic sense, or both types to enable human–computer interaction. The source of the touch under investigation could be animate (e.g. humans), inanimate (e.g. machines), or a combination of both. The items or environments being touched could be real, virtual, or a combination of both (M. Eid, Orozco, & Saddik, 2007), (Saddik, 2007). In addition, a haptics-based system may complement other sensory information such as vision, audition, or both, to make an environment appear more realistic.

Nowadays, haptics-based systems have had a significant impact in a variety of fields, such as surgical simulation, rehabilitation, technology designed to help the blind and visually impaired, education and training, entertainment and leisure activities such as video games, art and design,

online consumer activity, security, and mobile phones. A survey of haptic-based applications can be found in (M. Eid et al., 2007), (Saddik, 2007), (Abdulmotaleb El Saddik, Mauricio Orozco, Mohamad Eid, & Jongeun Cha, 2011) and (Escobar-Castillejos, Noguez, Neri, Magana, & Benes, 2016). Despite this, haptics-based applications are still in their infancy (Saddik, 2007), and their development is ongoing.

In this chapter we present the concept of haptics, its characteristics, classification and applications. Thus, the outline of the chapter is as follows: Section 2 defines the concept of haptics. Section 3 presents the components of haptics-based system architecture in a virtual environment. Section 4 provides the characteristics and classification of haptic devices. Section 5 presents examples of haptics-based systems in different areas. Finally, section 6 concludes the chapter with future research directions.

BACKGROUND: THE CONCEPT OF HAPTICS

The concept of haptics is derived from the Greek verb *haptesthai* which means ‘to touch’. It refers to the science of sensation and manipulation by touch for the purpose of perception or modification of the environment (Abdulmotaleb El Saddik et al., 2011), (M. Eid et al., 2007), (Mihelj, Novak, &

Begus, 2014). Touch is divided into two forms: the tactile (also called cutaneous) sense, and the kinesthetic (also called proprioceptive or force) sense (Abdulmotaleb El Saddik et al., 2011), (Benali-khoudja, Hafez, Alex, & Kheddar, 2004). The tactile sense refers to the registering of physical contact with a real object through skin receptors. It provides the individual with information about an object; this includes texture, pressure, temperature, wetness, softness, friction, vibration, and shape. Conversely, the kinesthetic sense of touch means feeling motion through awareness of position and movement of body parts as well as muscular efforts that are conveyed to the individual by sensory receptors in joints, tendons, and muscles when touching and manipulating items. The kinesthetic sense tells the individual about the movement of joints, velocity, muscle control, and weight. The human hand features both types of touch (Abdulmotaleb El Saddik et al., 2011), (Mihelj et al., 2014).

The term haptics was introduced in the field of psychology in the early 20th century to provide an explanation of the human perception of objects by touch. In the 1970s and 1980s, robotics researchers redefined the term to refer to the remote control of robots and their environment by touch (Abdulmotaleb El Saddik et al., 2011), (M. Eid et al., 2007). The early 1990s were the 'golden age' of haptics, due to the widespread appearance on the consumer market of different haptic devices such as the tactile mouse and the joystick. The field of computer haptics, introduced to integrate haptic

devices with computers (Abdulmotaleb El Saddik et al., 2011), (M. Eid et al., 2007), is associated with the design and development of algorithms and software to generate and display forces and tactile sensations to the user (Abdulmotaleb El Saddik et al., 2011).

HAPTICS-BASED SYSTEM ARCHITECTURE

The components of haptics-based system architecture in a virtual environment consist of the human operator, the haptic device, haptic rendering, the simulation engine, and audio-visual rendering, as shown in Figure 1.

The interaction between a human and a virtual environment in a haptics-based system is easy to understand. It is best described as follows:

Human Operator

The human operator manipulates the haptic device via the touch sense in either a tactile or kinesthetic manner, or both. Most haptics-based systems in a virtual environment interact with individual users through their hands, including fingertips and palms (see Figure 2), or through both hands (see Figure 13). However, the touch sense is distributed all over the body. As a result, Boian et al. have developed haptics-based systems that interact with an individual's foot (Boian, Deutsch, Lee, Burdea, & Lewis, 2003).

Figure 1. Haptics-based system architecture in virtual environments (Salisbury, Conti, & Barbagli, 2004)

Figure 2.

Haptic Device

Haptic devices are mechanical devices that enable communication between humans and machines by using the sense of touch (Sofronia, Savii, & Davidescu, 2010). A haptic device consists of one or more sensors and actuators. The sensors measure the interactions between a proxy and the environment, whereas the actuator applies the response mechanical action command (Abdulmotaleb El Saddik et al., 2011). Usually, haptic devices include a software toolkit to control the device by programming. Both the hardware and software of a haptic device are called the haptic interface (Robles-De-La-Torre, 2008). Haptic devices are classified according to the type of feedback into two categories: tactile feedback devices and force feedback devices. More information about haptic devices can be found in section 4.

Haptic Rendering

At the heart of a haptic-based application is haptic rendering. This enables a human to make use of a haptic interface in order to touch, feel, and manipulate virtual objects (Cagatay Basdogan & Mandayam A. Srinivasan, 2002). Haptic rendering refers to the group of algorithms that are used to calculate forces/torques and generate tactile or

kinesthetic sensations to signalize interaction between a proxy point inside the virtual environment and the virtual objects within the environment (Abdulmotaleb El Saddik et al., 2011), (Saddik, 2007), (Salisbury et al., 2004).

Haptic rendering is divided into three categories: collision detection algorithms, collision response algorithms, and control algorithms. The collision detection algorithm detects when and where a proxy meets a virtual object (Abdulmotaleb El Saddik et al., 2011), (Salisbury et al., 2004). The collision response algorithm calculates the ideal interaction force/torque for a force device and/or interprets tactile parameters, such as texture, as actuation commands for a tactile device (Abdulmotaleb El Saddik et al., 2011). The ideal reaction force cannot be applied to the user for various reasons, including limitations of the haptic device such as friction, inertia, and finite sensor resolution. In addition, there are limitations to the possible exerted force and direction by the haptic interface. Moreover, the interaction between the human operator and the haptic device is continued in time, whereas the interaction between haptic device and haptic rendering occurs in discrete-time signals. To counteract this, the control algorithm has to minimize the error between ideal and applicable reaction, with the provision of kinesthetic constraints on the

virtual environment and the decrease of inertia in free haptic movement (Abdulmotaleb El Saddik et al., 2011), (Salisbury et al., 2004).

The control algorithm for interaction between haptic device and virtual environment is divided into impedance control and admittance control. In impedance control, the user moves the haptic device, and it sends the haptic data to virtual environment application. In contrast, the users in the admittance control exert force on the haptic device for movement, which reacts as displacement for both input and output haptic data. This type of control provides free haptic device movement and produces movement with more force and stiffness (Escobar-Castillejos et al., 2016), (Mihelj et al., 2014). In the haptics-based system, haptic rendering draws comparisons between a proxy and all virtual objects. If a collision is detected, haptic rendering will calculate the reaction force/torque for kinesthetic sensation and/or actuator commands for tactile sensation. If no collision is detected, no reaction feedback will be calculated. This means that the user has free movement of the haptic device and does not affect any other virtual object. This haptic rendering loop is called the Servo Loop Rate or haptic update rate, and is repeated at specific time intervals such as 1 kHz (Abdulmotaleb El Saddik et al., 2011), (Saddik, 2007), (Salisbury et al., 2004).

There are different types of haptic rendering algorithms; they are classified according to feedback type to: virtual environment model and interaction methods. Haptic rendering produce different kinds of tactile stimuli such as temperature, texture, stiffness and friction. Each stimuli is rendered in a specific manner and presented through a specific display (Mihelj et al., 2014). In contrast, the kinesthetic rendering algorithms are usually different according to the number of Degree Of Freedom (DOF) for haptic device (Salisbury et al., 2004). Moreover, the haptic rendering algorithms are different according to virtual environment model such as rendering for object shape, deformable object, dynamic object, haptic playback, and haptic interaction through the network (Cagatay

Basdogan & Mandayam A. Srinivasan, 2002). Furthermore, the interaction method between haptic device and virtual environment is classified into: point-based, ray-based and 3D object made by a grouping of points, lines and polygon (Cagatay Basdogan & Mandayam A. Sinivasan, 2002), (Escobar-Castillejos et al., 2016).

Simulation Engine

This component computes the behavior of the virtual environment over a period of time. For example, visual rendering detects collisions among all objects in a virtual environment, while haptic rendering detects collisions in the immediate area of the proxy (Abdulmotaleb El Saddik et al., 2011). Moreover, the rendering update rates are different between haptic, visual, and audio rendering. The visual rendering update rate of 60 Hz is enough to display continuous motion on the screen that is visible to the human eye. Also, the audio rendering sample rate for a quality audio signal is 44.1 kHz for each audio frame which contains 10 ms (Taylor, Chandak, Antani, & Manocha, 2009). In contrast, the minimum haptic update rate in force feedback haptic rendering is 1 kHz. If the update rates fall below that value, the haptic device starts fluctuating and vibrating when we make virtual contact with solid surfaces (Saddik, 2007). A noticeable interaction delay is seen between the human operator and the force feedback from a haptic device (Robles-De-La-Torre, 2008). The best response for tactile vibration is higher than 300 Hz (Jeffrey J. Berkley, 2003). One way to solve the problem of the differences between the various rendering update rates is to use multiple threads (Cagatay Basdogan & Mandayam A. Srinivasan, 2002); however, the process of synchronizing different threads can be a challenge.

Audio-Visual Rendering

Audio-visual rendering calculates audio and graphic movement in a virtual environment (Abdulmotaleb El Saddik et al., 2011), (Saddik, 2007),

(Salisbury et al., 2004). Visual rendering (graphic rendering) refers to the generation of an image from a sense file through the use of computer programs with the ability to display tens of times per second. The sense file contains information about objects, texture, lighting, and shading as descriptions of virtual senses. Audio rendering provides realistic sound for interactive applications. It consists of two processes: propagation and rendering. The propagation process computes the path from the sound source to the listener and takes into account reflection and diffraction. The rendering phase generates specialized audio signals (Taylor et al., 2009).

HAPTIC DEVICES CHARACTERISTICS AND CLASSIFICATION

Haptic devices are input and output devices that trace the movements of the user (input) and that produce a touch sensation, either tactile or force (output) (Sofronia et al., 2010). This section provides characteristics and classification of haptic devices along with examples.

Characteristics of Haptic Devices

Each haptic device has different attributes, and these vary widely depending on the specific application of the device. The attributes of haptic devices are described in detail in (Abdulmotaleb El Saddik et al., 2011) and (Sofronia et al., 2010). Table 1 summarizes the characteristics of haptic devices and offers a short description of each characteristic.

Classification of Haptic Devices

Haptic devices are categorized into two groups based on the kind of feedback they provide; the two groups are tactile feedback devices and force feedback devices. These are described as follows:

Tactile Feedback Devices

Tactile feedback devices are designed to reproduce tactile parameters as accurately as possible. The parameters include texture, temperature, shape, roughness, pressure, rigidity, and vibration, among others; these are conveyed by skin receptors. However, no haptic device combines all tactile parameters (Benali-khoudja et al., 2004). Commercially available tactile devices are classified into vibration devices and pin array devices. Vibration tactile devices (also called vibrotactile devices) provide vibration upon touching virtual objects. An example is the CyberTouch by the company CyberGlove Systems, whereby vibrotactile stimulators on a glove produce vibration for the five fingers and the palm of the hand; see Figure 2. The tactile mouse is another example of a vibrotactile device. Its shape is similar to that of a standard mouse, but it produces vibration when the cursor is moved over a Graphical User Interface (GUI); one example is the iFeel mouse from Logitech (Abdulmotaleb El Saddik et al., 2011).

Pin array devices have generally advanced due to a significant amount of research performed in that field. They usually consist of a matrix of pins that differs in actuator technology, numbers of pins, space between pins, frequency, workspace, maximum force, resolution, and motion mode (raised/lower pins). In recent years, a number of pin array devices for blind individuals have been developed, such as VideoTIM3 and Braille Sense U2. VideoTIM3 from Abtim is a tactile device that converts printed text and simple graphics into a raised/lower matrix of pins (see Figure 3). The device consists of a camera held in the fingers and a refreshable matrix of pins to represent text in vibrotactile form (“VideoTIM3: READING DEVICE for the BLIND,” n.d.).

A further use of tactile feedback devices is to generate sensations of temperature and pressure. For example, CM Research, Inc. has developed the Displaced Temperature Sensing System (DTSS) that produces temperature feedback via a thimble (see Figure 4). The device can work as an input or

Table 1. Characteristics of haptic devices

Characteristic	Description
Workspace	The real-world space that can be reached by the end-effector of a haptic device. The workspace is classified into traditional and rotational. The point is represented in a traditional workspace as a Cartesian coordinate; it is represented in a rotational workspace as an angle range in pitch, yaw, and roll.
Degree Of Freedom (DOF)	Describes the amount of possible haptic device motion (right-left, up-down, forward-backward, and rotation) through the number of traditional and rotational variables in the device. For example, 3DOF means the device has three variables and can move right-left, up-down and forward-backward. Each haptic device has two sets of DOF: one for input (position sensing) and one for output (force feedback).
Position resolution	The smallest amount of end-effector movement that the device's sensors can detect. Haptic devices have two kinds of resolution: one for input (position sensing) and one for output (force feedback).
Precision	Accuracy of the haptic device. Haptic devices have two types of precision: one for input (position sensing) and one for output (force feedback).
Repeatability	Accuracy of identifying the physical position as being identical with the virtual position.
Grounding location	The base of the haptic device, either ground-based or body-based.
Maximum exertable force	The maximum output force that can be produced by a haptic device over a very small time interval such as milliseconds.
Minimum exertable force	The minimum output force that can be produced by a haptic device over a very small time interval.
Continuous exertable force	The output force exerted over an extended period.
Dynamic exertable force	Ratio of the maximum and minimum force.
Stiffness	The ability to mimic a rigid object.
Friction/damping	Force of resistance motion either with velocity (called damping or viscous friction) or without velocity (called Coulomb friction).
Backdrivability	Friction in the motors and cable of the haptic device.
Inertia	Mass at end-effector of haptic device.
Weight	The weight of the haptic device.
Interface	Item that connects the device with a computer, such as USB interface.
Bandwidth	Range of frequencies which end-effector provides force feedback.
Haptic refresh rate/ servo loop rate	Speed of haptic rendering from position sensors to force feedback response.
Maximum acceleration	Maximum changes in velocity.
Device latency	Total time from sending a command to the haptic device to receiving a response from the device.
System latency	The total time delay within the haptic virtual environment. IR includes sensing a position, computing the force feedback response, sending feedback to the device, and reading the next position.

Figure 3.

output channel and is operated through a controller unit or through a computer (Abdulmotaleb El Saddik et al., 2011). In addition, the researchers of the Toshiba Nuclear Engineering Laboratory have developed actuators in ring forms on a VPL DataGlove that interacts through pressure from the fingertips (Benali-khoudja et al., 2004).

Force Feedback Devices

Force feedback devices provide force that is conveyed to the human sensory receptors in tendons, joints, and muscles. Force feedback devices have two main functions: first, to determine the position of sensors and/or forces that are exerted by the human body; and second, to apply appropriate force and/or position of end-effectors to the user depending on the limitations of the haptic device.

Force feedback devices are classified according to design into ground-based and body-based devices. With ground-based force feedback devices, the base of the device is placed on the ground or on a desktop, and the user touches a part of the device; examples include joysticks, steering wheels, mice, linkage-based devices, and tension-based devices (also called string-based devices). On the other hand, body-based force feedback devices are worn or attached to any part of the body; examples include gloves, suits, and exoskeletal devices. Force feedback joysticks, mice, and steering wheel are cheap, portable, and are usually used for gaming, but they are not very accurate and allow only for a limited range of movement. For example, the G27 Racing Wheel from Logitech is a force feedback steering wheel haptic device; it uses force feedback to feel roads, bumps, and walls in racing games ("G27 Racing Wheel," n.d.). Logitech WingMan Force 3D joysticks are one example of force feedback joysticks. The device measures the angle or direction of movements and exchanges virtual objects on screen or video games. Also, the WingMan Force 3D joystick produces forces depending on user action, such as shooting, explosions, and acceleration.

Linkage-based devices consist of a robotic arm connected to an end-effector. The arm tracks the location of the end-effector and is capable of exerting a force to the end-effector (Jeffrey J. Berkley, 2003). There are three types of end-effectors in linkage-based devices: a knob, which the user grips by hand; the stylus/pen, which the user holds like a pen; and a thimble, into which the user inserts a finger. Linkage-based devices have various professional applications because they include more controls and haptic features; however, they permit only a single point of contact with the virtual environment. Commercially available linkage-based devices that are available and not limited are the Novint Falcon, Omega devices, Delta devices, Phantom haptic devices, and the Freedom 6S. The Novint Falcon from Novint Technologies has three arms, which extend from the device and which are joined to a knob for user control (see Figure 4).

The Omega 3 and the Delta 6 from Force Dimension are other examples of knob end-effector haptic devices. The design of these devices bears similarities to the Novint Falcon, but they provide high force feedback for a sustained period of time. The Omega 3 provides 3-DOF translation for both position sensing and force feedback. The Omega 3 and the Delta 6 are shown in Figures 5 and 6 respectively.

Examples of commercially available linkage-based force feedback devices with a stylus/pen end-effector are the Phantom Omni and the Omega 6 as shown in Figures 7 and 8 respectively. The Phantom from SensAble Devices, Inc. (now part of the Geomagic company) is a family of pen-based force feedback devices. It has three lines of commercially available haptic devices: the Phantom Omni (recently renamed the Geomagic Touch), the Phantom Desktop (recently renamed the Geomagic Touch X) and the Phantom Premium.

An example of a commercially available thimble-based force feedback device is the Phantom Premium 1.0 from SensAble Technologies, Inc. (now part of Geomagic). It includes a stylus

Figure 4. The Novint Falcon (El Saddik et al., 2011)

Figure 5. The Omega 3 (“Force Dimension - Products,” n.d.)

and thimble to produce forces to one fingertip (see Figure 9).

Tension-based devices consist of cables connected to a point of contact. The device senses the point position through determining the length of each cable. Moreover, tension-based devices produce force feedback on the point through creating tension in the cables. Tension-based devices have large workspaces, less inertia, and more accurate force feedback; they also provide forces to multiple points of contact (Jeffrey J. Berkley, 2003). A few commercially available tension-based devices

exist. For example, SPIDAR-8 was developed to manipulate virtual objects and produce forces via eight fingertips (thumb, index finger, middle finger, and ring finger on both hands) (Sato, 2002) (see Figure 10).

Examples of commercially available body-based force devices are the CyberGrasp and the Interactor vest. The CyberGrasp is an exoskeletal glove from CyberGlove Systems, which produces force feedback independently for each finger and the palm. Its full range motion of the hands includes shoulder, elbow, wrist, and finger (see Figure

Figure 6. The Delta 6 (“Force Dimension - Products,” n.d.)

Figure 7. The Phantom Omni (“Haptic Devices from Geomagic,” n.d.)

Figure 8. The Omega 6 (“Force Dimension - Products,” n.d.)

Figure 9. The Phantom Premium 1.0 (“Haptic Devices from Geomagic,” n.d.)

Figure 10. SPIDAR-8 (Sato, 2002)

11). The Interactor vest from Aura systems, Inc. is a rigid plastic backpack called a vest, which is worn over the upper torso. The device converts sound signals into forces and includes speakers with five levels of volume. The force feedback is increased according to the volume level. The interactor vest is plugged into the computer, TV, CD stereo, or video game (Doug Horton, 2004) (see Figure 12).

Figure 11. CyberGrasp (“cyberglovesystems products,” n.d.)

APPLICATIONS

There are different haptics-based systems developed for different areas. In this section, we present examples of haptics-based systems (see Table 2) that were proposed for medical simulation, rehabilitation, education and training, security, shopping, web application, collaborative environment, handwriting and emotion fields.

Figure 12. Interactor vest (Horton, 2004)

Table 2. Summary of haptics-based systems

Application Area	Description	Reference
Medical simulation	This approach enables a haptic palpation interaction for virtual reality-based medical simulation. The Palpation is a physical examination technique where objects are touched with fingers to determine their size, shape, consistency and location.	(Ullrich & Kuhlen, 2012)
rehabilitation	The system combines haptic, virtual reality and game technologies in order to assist patients in the training of the upper limb movement. The system provides visual, audio and force feedback.	(Covarrubias, Mansutti, Bordegoni, & Cugini, 2014)
education and training	Visual Haptic Jawi (HV-JAWI) is a handwriting training system designed for teaching Jawi cursive handwriting to primary school students. The application supports three different modes of handwriting training: fully guided, partially guided, and copy mode. In addition, the system supports assessment for student handwriting through online Jawi handwriting recognition and visualization of the student trajectory.	(Amin, Zaman, & Ahmad, 2013)
security	The system proposed incorporation of four haptic features in a haptic enabled authentication procedure, including stiffness, static friction, magnetic, and pop-through.	(Potocny, McNulty, Maiga, & Zadeh, 2015)
web application	The researchers proposed a framework to include haptic interaction in HTML based Web applications. Each HTML element provides specific type of force feedback. In addition, it supports independent haptic device	(Comai, Mazza, & Guarinoni, 2012)
collaborative environment	The haptic researchers have developed Collaborative Haptic Audio-Visual Environments (C-HAVE) that allow multi-users, who each has a haptic interface, to manipulate shared objects in the environment, either collaboratively or remotely.	(Abdulmoteleb El Saddik et al., 2011)
emotion	Proposed a system that produces a haptic mirror for visually impaired. The system captures facial expressions directly from a webcam and presented through haptic interface.	(Yasmin, McDaniel, & Panchanathan, 2014)

FUTURE RESEARCH DIRECTIONS

Recently, contactless haptic devices are a new trend in the development of haptic devices. They produce tactile feedback without any physical contact with the user. The contactless haptic devices depend on different technology such as air-jet, acoustic radiation pressure and laser (Arafsha, Zhang, Dong, & Saddik, 2015).

Furthermore, to develop more complex haptic applications, haptic multimedia was introduced; it is defined as “the acquisition of spatial, temporal, and physical knowledge of the environment through the human touch sensory system and the integration and/or coordination of this knowledge with other sensory displays such as audio, video, and text in a multimedia system” (M. Eid et al., 2007). Multimedia haptic applications are also referred to as Haptic Audio-Visual Environment (HAVE) (Saddik, 2007). Moreover, the term of

tele-haptics was introduced for transmission haptic sense over network (Shen & Shirmohammadi, 2008). Recently, the field of affective haptics was introduced for capture and display emotions through the sense of touch; it is defines as “the acquisition of human emotions through the human touch sensory system, the processing of emotion related haptic data to detect affect, and the display of emotional reactions via haptic interfaces. Emotions may be solely communicated through the sense of touch or coordinated/integrated with other sensory displays (such as audition or vision) in a multimedia system” (M. A. Eid & Osman, 2016).

Finally, the research trend in the development of haptics-based systems is the focus on haptic interaction for mobile device such as smartphones and tablets. The haptic interactions for mobile devices are not limited to simple tactile vibration, but also the proposed kinesthetic feedback can potentially be incorporated into mobile devices

(Kwon, Yang, & Cho, 2010). For example, researchers have proposed a haptic stylus to access visual images from smartphones. The haptic stylus generates force and tactile feedback (Tian, Song, & Chen, 2016).

KEY TERMS AND DEFINITIONS

Human–Computer Interaction (HCI): The study of how user interacts with computers.

Haptics-Based System: A software that uses touch sense for interacting with the user.

Haptic Device: A machine that uses touch sense as input, output or both.

Haptic Rendering: A group of algorithms that are used to calculate and generate tactile or kinesthetic sensations.

Kinesthetic Sense: Information about touch sense through motion of joints, tendons, and muscles during touch object motion.

Tactile Sense: Information about touch sense through a physical contact between object and surface of the body. This information includes texture, pressure, temperature, wetness, softness, friction, vibration, and shape.

Virtual Environment: A software that simulates the real world or imagination.

The Holon/Parton Structure of the Meme, or The Unit of Culture

J. T. Velikovsky

University of Newcastle, Australia

INTRODUCTION

This chapter identifies the formal structure of *the unit of culture*,¹ a unit also known as the *meme* (Dawkins, 1976) as: the *holon/parton* - as a resolution of a longstanding open problem in both Information Science and Information Technology² and across all domains of culture including the media, the arts, entertainment and science. The holon/parton is a fractal hierarchical structure, the formation of which is governed by the laws of physics as proposed in (Wilson 1998). Previously there was no universal definition of the unit of culture, resulting in more than three hundred varying definitions of culture (Baldwin et al 2006) and no consensus (van Peer et al 2007).

This chapter thus presents *a universal structure for the unit of culture* (the meme) in order to facilitate commensurate empirical analyses of culture (and its component parts, or units) across disciplines - and to enable structural, functional and behavioral comparisons between biocultural artifacts (memes). This allows for the accurate tracking and understanding of the transmission of culture including within the domains of Information Science and Information Technology. The structure of the unit of culture - viewed as the *holon-parton* - is a conceptual, theoretical, practical and scientific tool for identifying and analyzing units of culture (as parts and also as wholes) within all symbol systems in culture.³

BACKGROUND TO THE PROBLEM

Knowledge (i.e., retained information, or culture) emerges from creative⁴ biocultural human systems at an exponential rate. As two examples: the number of published scientific papers doubles every nine years (Bornmann & Mutz, 2014) and the number of new books published each year (approximately 700,000 per year in the U.S.) doubled in the five years from 2008 to 2012 (Bowker, 2013). The question emerges: What structural rules (laws) govern the formation of these units of culture (i.e., research papers, chapters, books, phrases, words) - or ideas, processes and products?

Knowledge is retained information, and is considered 'culture'. However 'culture' has been a problematic term as there is currently no consensus across all of domains and disciplines on the term. In 1952, 164 definitions of culture were extant (Kroeber & Kluckhohn, 1952) and in 2006 the list had been extended to over 300 definitions (see Baldwin, Faulkner, Hecht, & Lindsley, 2006, pp. 139-226). The article 'Evolution of Culture, Memetics' in the *Encyclopedia of Complexity and Systems Science* states 'The lack of a universally accepted meme definition and the vagueness of meme boundaries... indeed make empirical studies less evident' (Heylighen & Chielens, 2009, p. 3217).

The following identification of the structure of the unit of culture (the meme) - namely the *holon/*

parton - provides a solution to the problem of defining and thus analyzing culture and therefore has universal (multi-, cross- and trans-disciplinary) applications in allowing for comparative empirical studies of culture (or knowledge, or memes).

THEORETICAL PERSPECTIVE

The theoretical perspective adopted in this chapter is Evolutionary Systems Theory.⁵ *Introduction to Systems Philosophy: Toward a New Paradigm of Contemporary Thought*, Laszlo (1972) incorporates Living Systems Theory (Miller, 1968)⁶ and Bunge's hierarchical structures (Bunge, 1969) to provide a framework for understanding universal structures spanning from subatomic physics, through biology, chemistry, organisms, and social systems to the cosmos (Laszlo, 1972, pp. 29, 177-180). An illustration of this view is shown in Figure 1.

In this view the largest-to-smallest levels of structural hierarchical organization are all governed by three laws of physics, namely three laws of holarchies (see below). Laszlo (1972) employs Koestler's holon theory in systems (Laszlo, 1972, pp. 55-118, 252, 255, 272-114), as Koestler had previously extended General Systems Theory (Koestler, [1978] 1979, pp. 31-32; von Bertalanffy, 1950) from biological systems to social holarchies (i.e., hierarchies of social holon/partons) and to linguistic hierarchies (Koestler, [1964] 1989, pp. 287-290; [1967] 1989, pp. 103, 198-109; [1978] 1979, pp. 27-62). As noted in the *Key Terms and Definitions* section (below) in simplest terms the *three laws of holarchies* (three key behaviors of holon/partons) are as follows.

As *units*, holon/partons:

- Compete, and/or co-operate (and/or engage in *co-opetition*) 'sideways' – namely with other holon/partons on the same level;
- Integrate 'upwards' – namely into the larger holon/parton 'above'; and
- Control and command the holon/partons on the level 'below' – namely their own component holon/partons

Figure 1. The Evolutionary Systems View, from the multiverse through to subatomic particles (derived from Laszlo 1972); image copyright IGI Global (Velikovsky 2016, p. 211)

This basic concept of 'the three laws of holarchies' is illustrated in Figure 2.

These three laws are laws of physics (and of systems) applying both to biology and also as seen here in bioculture (aka 'culture') a possibility suggested in *Consilience: The Unity of Knowledge* (Wilson, [1998] 1999, pp. 60, 291, 293).

Figure 2. The three laws of holon/partons, or, holarchies (derived from Koestler 1964-1978); image copyright IGI Global (Velikovsky 2016, p. 212)

THE DEFINITION OF THE UNIT OF CULTURE AS: THE HOLON/PARTON

The definition of the unit of culture (the meme) is thus: the holon/parton. The holon/parton *structure* of the unit of culture (meme; i.e. idea, and/or process, and/or product) can be viewed in Figure 3.

This structure is fractal (self-similar on smaller scales). This is not to imply that *all* units of culture can (nor should be) be subdivided into exactly *two* parts infinitely; the number of components on each lower (smaller) levels of the holarchy may increase exponentially.⁷ As one example: in a single novel there may be around 100,000 words;

in a 90-minute movie (at 24 frames per second) around 130,000 still-image frames.⁸

THE HOLON/PARTON AS THE UNIT OF CULTURE IN VARIOUS COMMUNICATION MEDIA

With the above holon/parton schema of all (bio) culture in mind, below are hierarchical templates for various communication media as memes (units of culture) and their component units (on the levels below) each considered as holon/partons.

Figure 3. The holon/parton structure of the unit of culture - or the meme (idea, process, product); image copyright IGI Global (Velikovsky 2016, p. 217)

The three laws of holarchies apply to the units on each level; namely each of these whole units: (1) integrate *upwards*; (2) compete and co-operate *sideways*, and (3) control and command, *downwards*.

The Novel

- All extant novels
- All libraries, and all retail outlets for novels
- Library, or retail outlet
- All novel genres
- Specific Genre
- Specific Novel
- Chapter
- Paragraph
- Sentence
- Word
- Letter (and punctuation mark, including spaces)
- Idea

As an analysis of the laws governing these holon/partons: individual *novels* compete with other individual novels for reader attention, thus for canonical status, and for both library and retail shelf-space in the field (Boyd, 2009; Van Peer, 1996, 1997; Moretti 2000); as do transmedia stories, literary genres, and sub-genres; the specific words, sentences, paragraphs and chapters (and also any images) that have survived the creation and editing process are those retained in the published work; in the completed work they also co-operate (or, *operate together*) to attract the attention of; to convey information and meaning to; and, possibly to evoke emotional or intellectual engagement (the 'flow' state, or Narrative Transportation) in the reader, i.e. the audience, or field (Boyd, Carroll, & Gottschall, 2010; Velikovsky 2014a).

Movie

- All extant movies
- All movie genres

- Specific Genre
- Specific Movie
- Act
- Sequence
- Scene
- Shot
- Action, and/or Dialogue (e.g. line of dialogue)
- (Dramatic) beat
- Single (still image) frame
- Idea

As with the 'Novels' example above each unit (or holon/parton) on the same holarchic level of a movie *integrates* 'upwards'; *competes/co-operates* 'sideways'; and also *controls* (i.e., provides organizing principles namely sets of 'rules' for) the units on the level 'below' it.

Videogame

- All extant videogames
- All videogame genres
- Specific Genre
- Specific Videogame
- Game Level
- Game Environment
- Building
- Room
- Puzzle/Hazard
- Game event
- Idea

Theatre (Play)

- All plays
- All play genres
- Specific Genre
- Specific Play
- Act
- Scene
- (Dramatic) Beat
- Moment
- Idea

Popular Song

- All popular songs
- All popular song genres
- Specific Genre
- Specific Song
- Intro / Verses / Chorus / Bridge / Solo / Coda (or commensurate, or alternate parts)
- Word / Chord
- Letter / Musical note/ Beat
- Idea

Poem

- All poems
- All poetic genres
- Specific Genre
- Specific Poem
- Stanza
- Word
- Letter
- Idea

Joke

- All jokes
- All joke genres
- Specific Genre
- Specific Joke
- Setup / Feed / Punchline (or commensurate or alternate parts; e.g., one-liner)
- Word
- Idea

Spoken Language

- Phrase / Sentence
- Word
- Morpheme
- Phoneme

Science

- All science
- Domain of science

- Scientific discipline
- Scientific paradigm
- Metatheory
- Theory (including: Laws, Assumptions, Initial Conditions)
- Objective Phenomena
- Fact
- Idea

Religion

- All religions
- Specific Religion
- Specific Faith
- Metaphysics
- Scripture
- Idea

Bioculture is composed of extrasomatic symbol systems (e.g., written and spoken language, mathematics, musical notation, paintings, drawings, and so on). This holon/parton (and *holarchy*) structural tendency of symbolic biocultural artifacts as outlined above has been hinted at by prior theorists including Herbert Simon (1996):

Symbolic Systems... systems of human symbolic production. A book is a hierarchy in the sense in which I am using that term. It is generally divided into chapters, the chapters into sections, the sections into paragraphs, the paragraphs into sentences, the sentences into clauses and phrases, the clauses and phrases into words. We may take the words as our elementary units, or further subdivide them, as the linguist often does, into smaller units. If the book is narrative in character, it may divide into "episodes" instead of sections, but divisions there will be. The hierarchic structure of music, based on such units as movements, parts, themes, phrases, is well known. (Simon, 1996, pp. 187-188)

This holon/parton structure Simon (1996) indicates (without labelling it as such) can be viewed as in Figure 4.

Figure 4. A diagrammatic analysis of the holon/parton structure of three paragraphs of text; image copyright IGI Global (Velikovsky 2016, p. 220)

Evolutionary psychologist Steven Pinker states: (with 'chunks' here considered as units)

Several clauses are joined or embedded in a sentence; several sentences make up a paragraph; several paragraphs make up a section, several sections a chapter, several chapters a book. A text with this hierarchical structure is easy for a reader to assimilate because at any level of granularity, from clauses to chapters, the passage can be represented in the reader's mind as a single chunk... (Pinker 2014, p. 142)

THE HOLON/PARTON AS THE UNIT OF STORY (THE NARREME)

The unit of story (unit of narrative) has been discussed by Barthes (1966), (Dorfman, 1969) and many other researchers however it is clear that the narreme was not satisfactorily defined by Barthes in 1966 nor since (Baikadi & Cardona-Rivera, 2012). Stories (narratives) are part of bioculture. Since stories are composed of ideas, words, phrases, (and/or cinema shots, images, sounds) and so on, the unit of culture (the meme

- as holon/parton) can thus be applied to the *unit of story* (the narreme).

Boyd (2009) notes narrative plots are structured focused on agents (characters) with an: intention, action, obstacle/s, and outcome. A story (or narrative), and its component parts, namely *scenes* (both considered as holon/partons) display a fractal structure - namely both the story (the *whole*) and the scene (the *part*) include the characteristics of: intention, action, obstacle, and outcome.

ISSUES, CONTROVERSIES, AND PROBLEMS

The Complexity perspective and the use of Systems Theory is no longer seen as controversial in the Social Sciences given 'The Complexity Turn' of the mid-1990s⁹ however the integration of the Systems Model of Creativity and the Evolutionary Systems Theory perspective has yet to become widespread in Mass Communication Studies (see also: Fulton & McIntyre, 2013).

Memetics has been in a (Kuhnian) pre-paradigm state since Dawkins (1976) as the universal structure of the unit of culture (the meme) has

not previously been identified; however *the holon/parton* presents a solution to this problem.¹⁰ While not every single retained cultural artifact in existence adheres to the holon/parton structure when analyzed, canonical cultural artifacts (as opposed to ‘archive’ *sensu* Moretti 2000) do so.

FUTURE RESEARCH DIRECTIONS

Future research directions and applications of the structure of the unit of culture (the meme) in Information Science and Information Technology include empirical investigations on the number and the type (quantitative and qualitative analyses) of units of culture (as holon/partons) that compose those canonical memes (i.e., the ideas, processes and products that are retained and reproduced in culture) compared to those in the non-canonical (archive) units which are de-selected by the field (audience) for that domain of culture.

The 2011 article ‘Can We Measure Memes?’ (McNamara, 2011) asks if fMRI technology can measure memes in the brain, proposing the distinction of *internally* and *externally* represented memes (‘i-memes’ and ‘e-memes’). The article concludes that if memes (units of culture) *can* be accurately defined and if cognitive science can thus measure memes this would be a significant advance with far-reaching implications in cultural evolution for many domains and disciplines well beyond mere questions around how language works (McNamara 2011, online).

CONCLUSION

This chapter identifies the unit of culture aka the meme (an idea, a process or a product) as the holon/parton (and thus the holarchy). This Evolutionary Systems Theory view of bioculture adopts an Applied Evolutionary Epistemology approach (Gontier 2012) and aims to provide a solution of the problem of the definition of the

term ‘culture’ and thus a theory to enable accurate empirical transdisciplinary investigations of bioculture across all communication media including the arts, entertainment and sciences - including Information Science and Information Technology.

This holon/parton view of units of culture supports E. O. Wilson’s hypothesis in *Consilience* (Wilson, 1998) that laws of physics (laws of Evolution and Systems Theory - namely the three laws of holarchies) apply to the formation and growth of bioculture, illuminating the unit of culture (the meme) where ideas, processes and products correlate respectively with: Worlds Three, Two, and One in Sir Karl Popper’s ‘Three Worlds’ theory (Popper, 1978b; Boyd 2016).

KEY TERMS AND DEFINITIONS

Creativity: The standard definition of creativity is ‘original and useful’ namely a biocultural artifact (i.e., idea, process, product) judged ‘original and useful’ (‘novel and appropriate’) by a consensus of the audience (i.e. the field) for a specific domain in culture (Runco & Jaeger, 2012). Examples of domains in culture include movies, literature, popular music, videogames, astronomy, physics, chemistry, biology, psychol-

ogy, sociology, anthropology and all their various subdomains (including genres and subgenres).

Culture: ‘Culture’ is knowledge encoded in symbol systems in the form of ideas, processes and products (Csikszentmihalyi, 1996) including in science, the arts, media, religion, and languages. Examples of ideas include scientific theories (e.g., gravity, general and special relativity, evolution) and also literary and media characters and narratives (Sherlock Holmes, Anna Karenina, Harry Potter); examples of processes include cognitive processes: writing an email, having a conversation, reading a book and in science, pasteurization; examples of cultural products include the hand-axe, the spear, the wheel, words, books, movies, songs, the printing press, the telescope, the microscope, the car, the computer and iPod. As there is no culture without biology a synonym for ‘culture’ is ‘bioculture’.

Evolution (Biological, Cultural, Cosmic): Evolution can most simply be defined as ‘descent with modification’ (Chaisson, 2001; Darwin, 1859). Here the concept of evolution includes the (post-1940s) Modern Evolutionary Synthesis (aka ‘Neo-Darwinism’) including Multilevel Selection Theory (Gontier, 2012). ‘The evolutionary process requires variation, differential survival and reproductive success, and inheritance’ (Capra & Luisi, 2014, p. 200; see also Dennett, 1995, p. 343). Laszlo (1972) explains atoms, biology and social systems as classes of natural (and sometimes designed) systems ‘sharing invariant fundamental properties’ (Laszlo, 1972, p. 56) and demonstrates that evolution occurs across natural systems (Laszlo, 1972, pp. 57-117).¹¹ Systems and artifacts (inputs and outputs) are selected (or deselected and thus ‘falsified’) by their environment (Popper 1999). The iterative and recursive Evolutionary Algorithm (namely: variation, selection, transmission) satisfies rather than optimizes.¹²

Holarchy: Koestler defines a holarchy as a hierarchy of self-regulating holons (Koestler, 1967, p. 103). Holarchies function according to the three

laws of holarchies - which are also three laws of evolution in Systems Theory (see Laszlo, 1972, pp. 55-118, 176-180) - namely: (1) competition and/or cooperation (and/or co-opetition), 'sideways' with other holon/partons on the same level; (2) integration upwards, into the larger holon/parton on the level 'above'; and (3) control and command of holon/partons on the level 'below' (Koestler, 1964, 1967, 1978).

Holon: (sensu Koestler 1967) 'A holon ... is something that is simultaneously a whole and a part. and a part' (Koestler 1967, p. 48).

Holon/Parton: A portmanteau synthesis of the terms holon and parton. A consilient (science and the arts) synthesis of these two terms used herein is 'holon/parton' as this term emphasizes the dual or 'Janus-faced' (Koestler, 1979, p. 27) nature of these whole/part entities; they are a whole and also a part at the same time in both biological and in socio-cultural systems and also in biological and biocultural units.

Meme: The unit of culture (Dawkins 1976). Identified (thus defined) here as: the holon/parton (see: Velikovsky 2016).

Parton: (sensu Feynman 1975, 2005) The term in subatomic physics that Richard P. Feynman (Feynman, 2005, p. 278) created for the equivalent structure of: the holon.

Systems Theory: The study of systems and their environments - including system inputs, outputs, relations and interactions including the concept of emergence where the whole system (its structure, function and behavior) is more than the sum of its parts. For reviews of Systems Theory, Complexity and Emergence in biology and culture see (Sepänen in Altmann & Koch, 1998, pp. 180-302), (Sadowski, 1999, pp. 7-10), (Gershenson & Heylighen. (2005). (Warfield, 2006, pp. 38-46), (Lin, Duan, Zhao, & Xu, 2013, pp. 1-22). Mobus & Kalton, 2014, 32-40.

Transmedia: A narrative extended across more than one media (e.g., across a movie, novel, videogame, nonfiction documentary and so on). Adaptations of a narrative from one media to another (e.g. novel-to-film) and prequels and sequels

in the same media are not transmedia (see: Dena, 2009; Jenkins, 2011; Polson, Cook, Brackin, & Velikovsky, 2014; Kerrigan & Velikovsky, 2015).

- ³ This structure of the unit of culture synthesizes concepts from (Koestler 1967) and Feynman (2005).
- ⁴ See the standard definition of creativity (Runco & Jaeger, 2012).
- ⁵ See the (evolutionary) DPFi systems model of creativity (Csikszentmihalyi 1988, 1996, 2014) and Csikszentmihalyi, M., & Nakamura, J. (2006). See also, Simonton (2012a, 2012b), Sawyer ([2006] 2012, p. 123, on the DPFi 'sociocultural' model of creativity), and see McIntyre (2012) and also Macdonald (2013 p. 123) on the same Domain, Person, Field interaction (DPFi, or DIFi) systems model of creativity.
- ⁶ See also the subsequent updated edition, *Living Systems* (Miller, 1978).
- ⁷ In human biology for example there can be around 10^{14} units when different levels (and units) emerge in the holarchy: there are around 10^{14} atoms in cell (Helmenstine, 2014), around 10^{14} cells in a human body (Richards, 2012, p. 70) and around 10^{14} synapses (connections between neurons) in the human brain (Zimmer, 2011). See also (West & Brown, 2005).
- ⁸ *Amazon.com* notes that the 'average' book on Amazon has 64,500 words (Habash, 2012).
- ⁹ See (Blaikie, 2007, pp. 206-214).
- ¹⁰ One reason for the abandoning of the *Journal of Memetics* (JoM, 1997-2005) and dispersal

of the nascent field of Memetics is that: the structure of the meme (the unit of culture) was not previously identified. Dennett noted in 1995 that ‘The prospects for elaborating a rigorous science of memetics are doubtful’ (Dennett, 1995, p. 369). Various scholars in Memetics (e.g., Blackmore, Farncombe, Dennett et al.) are persisting in solving this hard problem (see Hull, 1982 in Dennett,

1995, p. 352); see also for example (Velikovsky, 2014a, 2014b).

¹¹ Herbert Simon (1996) distinguishes between natural and artificial systems (Simon, 1996).

¹² Simon (1991) rightly notes: ‘natural selection only predicts that survivors will be fit enough, that is, fitter than their losing competitors; it postulates satisficing, not optimizing’ (Simon, 1991, p. 166).

ICT Standardization

Kai Jakobs

RWTH Aachen University, Germany

INTRODUCTION

According to the definition adopted by the International Organization for Standardization (ISO) a standard is a document, “established by consensus and approved by a recognized body, that provides, for common and repeated use, rules, guidelines or characteristics for activities or their results, aimed at the achievement of the optimum degree of order in a given context” [ISO, 2015]. The fact that standards are established ‘by consensus’¹ distinguishes them from legislation. Typically, the use of standards is voluntary. However, through legislation they may become mandatory (e.g. many health and safety standards) or ‘quasi-mandatory’ (e.g. Harmonized European Standards).

Standards – in a very general sense – have been with humankind for quite some time. About 4,000 years ago the first alphabets emerged, enabling new forms of communication and information storage. Around the 7th century BC the Lydians invented the first coin-based currency; it established the basis for easier inter-regional trading. The advent of the railroad in the 19th century resulted in a need for technical standards, e.g. those that enabled compatibility between individual parts of technical artifacts, defining e.g. the width of railway gauges, the diameter of screws, etc. This was once more reinforced when mass production generated a demand for interchangeable parts. In parallel, the invention of the electric telegraph in 1837 triggered the development of standards in the field of electrical communication technology. In 1865, the International Telegraph Union – to become the International Telecommunication Union² (ITU) in 1932 – was founded by twenty nation states. The other major international standards setting bodies, the International Electrotechnical

Commission (IEC) and ISO, were founded in 1906 and 1947, respectively.

In the field of Information and Communication Technologies (ICT) international standards are the major mechanism to ensure interoperability between systems. Frequently, ICT standards also describe a commonly agreed platform upon which innovations can be based. Moreover, standards in general are a valuable means of technology transfer. They have also been used as policy tools – for example, they are a major pillar of the European Single Market. Standards’ potential economic implications must also not be under-estimated. A new standard may be used to extend a market, or even help open up a new one. Intellectual Property Rights (IPR), mostly patents, also play a major role here. That is, standards must also be considered as strategic tools. The above suggests that standards are not just technical documents but that they may have ramifications well beyond technology. Accordingly, they should no longer be considered as pure ‘public goods’, i.e. as something that is non-rival and non-excludable [Deneulin & Townsend, 2007]. Rather, these days standards are typically seen as impure public goods, or club goods; they are non-rival and excludable, just like e.g. satellite TV, cinemas or private parks (see also e.g. [Hawkins, 2009]). This is largely due to the frequent incorporation of IPR into standards.

Against this background, this chapter will first briefly look at the links between standards and standardization, innovation and economics. It will then offer a brief description of a typical standards setting process. The complex ‘web’ of Standards Setting Organizations in the ICT sector will be discussed next. Subsequently, a flexible tool to describe the characteristics of an SSO will be discussed. It can be deployed by firms to

DOI: 10.4018/978-1-5225-2255-3.ch406

identify the SSO that is best suited for a planned standardization activity. This selection is only part of the fairly complex task of standardization management, which will be described next. Finally, the chapter will briefly discuss national standardization strategies.

BACKGROUND

Not so long ago standardization and innovation were considered as almost mutually exclusive (see e.g. [Hemenway, 1975], reported in [Farrell & Saloner, 1985]). This has changed by now. In fact, close links between standardization and innovation may often be identified. Today, standardization is no longer considered an impediment to innovation. However, the unqualified claim that ‘standards foster innovation’ does not fully reflect reality either. Swann & Lambert [2010] observe that standards do both – enable and constrain innovation – but that the enabling aspect is much more important. Specifically, they note that “... *standardization does constrain activities but in doing so creates an infrastructure to help trade and subsequent innovation. Standardization is not just about limiting variety by defining norms for given technologies in given markets. Standardization helps to achieve credibility, focus and critical mass in markets for new technologies*” (p. 370).

That is, especially in the field of ICT many standards describe a commonly agreed platform upon which innovations can be based and marketed. Accordingly, standards may be, and indeed are, used as strategic tools. For example, a new standard can extend a market, or even help open up a whole new one (just think what GSM did for mobile communication). On the other hand, backing and subsequently being locked into a ‘wrong’ technology (i.e. one that does not get standardized) may well ruin at least smaller companies.

What’s more, “*Standards are not only technical questions. They determine the technology that will implement the Information Society, and consequently the way in which industry, users, consumers and administrations will benefit from it*” [CEC, 1996; p. 1]. That is, those that develop ICT standards today at the same time shape much of the ICT environment we all will use in the future. And if they do their job properly, i.e. if they develop standards that meet the needs of all stakeholders (including e.g. individuals, communities, businesses, and governments) society at large stands to benefit.

From a macro-economic perspective, DIN [2004] finds that “*standardization contributes to GDP growth at the rate of about one percentage point per annum*”. This is in line with a number of similar studies from other countries. Blind [2013] reports that the contribution of standards to the growth rate in different countries was equivalent to 0.9% in Germany, 0.8% in France and Australia, 0.3% in the UK and 0.2% in Canada. Adopting a micro-economic perspective, ISO [2011, 2012] did a number of studies in companies from different business and countries. Based on Porter’s value chain [Porter & Kramer, 2011] these studies show that the implementation of standards can provide economic benefits to firms between 0.5% and 4% of their annual revenues.

By now, participation in standards setting has become a major strategic tool for many firms. Frequently, a firm’s aim will be to influence the process for its own benefit. This holds particularly – though by no means exclusively – for large companies. Other potential motivations include e.g. networking, intelligence gathering and increasing credibility (see e.g. [Jakobs, 2013]).

In addition, standards are a valuable means of technology transfer, which makes them also relevant also for academia and research institutions. Standardization also provides a legal platform for co-operation with competitors and (potential) customers.

Figure 1. The ICT Standardization Universe in the 1970s (adapted from Jakobs & Kritzner, 2009)

SETTING ICT STANDARDS

The ICT ‘Standardization Universe’

Back in the 1970s, the standardization universe was still rather simple and well-structured. Telecommunications standards (called ‘Recommendations’) were developed by the Consultative Committee for International Telephony and Telegraphy (CCITT; the predecessor to ITU-T), a then quasi-monopoly UN organization. This sector was almost completely separate from IT standardization, which was lead by ISO and its national member organizations. That is, standards were almost exclusively set by ‘formal’ Standards Developing Organizations (SDOs; i.e. e.g. ISO, CCITT, ITU-T). The one private consortium in existence was the European Computer Manufacturers Association (ECMA). Figure 1 depicts this situation.

These days, an extensive web of Standards Setting Organizations³ (SSOs) are active at the international (e.g. ISO and ITU), the regional (e.g. the European Telecommunications Standards Institute, ETSI) and the national level (e.g. the American National Standards Institute, ANSI; see Figure 2). Their output is frequently referred to as ‘de-jure’ standards, although these standards do

not have any regulatory power per-se. In parallel, a plethora of private industry fora and consortia (a couple of hundred), such as the World Wide Web Consortium (W3C) and the Open Mobile Alliance (OMA), produce what is often termed ‘de-facto’ standards. The processes through which both types of standards are developed are typically very similar (see below). The required level of consensus may differ, though. It should be noted that both ‘de-facto’ and ‘de-jure’ standards may gain some regulatory power, e.g. through references in legal documents.

Figure 2 also shows that the former clear-cut distinction between Information Technology on the one hand and the Telecommunication sector on the other has largely disappeared. This reflects the situation on the market, where the two sectors are hardly distinguishable any more (virtually every computer can communicate and every smart phone is also a small computer).

This highly complex structure has led to a considerable degree of fragmentation. Frequently, several SSOs are active in similar or overlapping domains. As a result, there may well be competition either generally between SSOs that cover similar ground or temporarily between different SSOs’ Working Groups working on similar projects. Consequently, there is an urgent need

Figure 2. The ICT Standardization Universe today (excerpt; adapted from Jakobs & Kritzner, 2009)

for co-ordination. Given the diverse nature of the individual SSOs (see also below) this may be extremely difficult to achieve.

Nevertheless, a comparably high level of co-ordination exists between ISO and the regional and national SDOs, to avoid inconsistencies and contradictions between international, regional and national standards. This coordination is based on the WTO's agreement on 'Technical Barriers to Trade' [WTO, 2015]. In a nutshell, it states that national bodies shall use international standards and remove contradicting national ones whenever possible. Figure 3 shows different types of bilateral agreements.

Following a different approach, the Global Standards Collaboration (GSC; see Figure 2) provides for the regular exchange of work programs and other information between its members, the

regional Telecommunication standards bodies and the ITU. ETSI Partnership Projects represent a related approach to co-ordination. These projects coordinate groups of regional SDOs working towards a common goal. 3GPP⁴, which is active in the field of wireless communication, is a prominent example.

Coordination of the activities of consortia working in overlapping fields is not always desired; some consortia were primarily established to compete with others. Where this is not the case, cooperation is mostly based on different types of bilateral liaison agreements. These agreements are, in most cases, either rather generic (e.g. a general Memorandum of Understanding) or very specific (e.g. relating to one specific standard). Overall, cooperation between consortia is not nearly as pronounced as between SDOs.

Figure 3. Different types of bi-lateral agreements between SSOs (adapted from Jakobs, 2013)

The Standards Setting Organizations (SSOs)

The characteristics of individual SSOs may differ considerably, in various respects. This holds for both SDOs and consortia. Therefore, the traditional distinction between these groups is not overly helpful. A more flexible and meaningful approach was introduced by Updegrove [2006]. It is based on a set of attributes that can be applied to describe an SSO. These attributes fall into four categories:

- General
- Membership

- Standards setting process
- Output

An attribute is a tuple <type, value>. Table 1 summarizes the defined types and provides a brief description for each; the values need to be determined individually for each SSO.

An SSO's IPR policy is probably the single most important criterion. In principle, each party that contributes to the work of an SSO on a specific standard is required not only to disclose any IPR that is relevant for this standard, but also to license it. This holds particularly (though not exclusively) for any 'Standards Essential Patents' (SEPs). If a

Table 1. SSOs' attributes and descriptions (taken from Jakobs & Kritzner, 2009)

General	Description
Internal	
overall goals business models	These provide some general background information.
governance	'Governance' is important for those who wish to influence the goals and activities.
finances staffing	'Finances' and 'staffing' are important to evaluate the chances of an SSB's long-term survival.
IPR policy	IPR policy should not deter any stakeholders.
External	
reputation	Joining an SSB with a poor reputation, or with a poor record, will not make too much sense in many cases.
competition	Do competing SSBs exist, or are they likely to emerge in the near future?
liaisons	Is the SSB prepared to co-operate with other entities?
Membership	Description
Quantitative: • overall # of members • membership levels • membership fees	Provides some information about the relevance of the SSB. In many cases, some are more equal than others. Who decides, who does the work, and are these the same? May also help to determine a prospective new member's chances of active contribution and decision.
Qualitative: • key players involved? • 'active' members • individuals' capacity	Are those organizations important in the specific sector on board? Which are missing? Which members are prepared to invest resources into activities like e.g. editing documents, leading WGs, etc.? Is there a 'corporate whip', or do reps decide independently? What are the SSB's rules?
Standards Setting Processes	Description
Timing: • time for TC/WG establishment, • average time until finalization	Indicates the effort/time required to finalize a new standards project. Helps to determine whether or not a (perceived) window of opportunity can be met.
Process characteristics: • openness • transparency • required level of consensus • observation of due process • decision mechanism	Basically to determine how fair the process is? Do I have a say, or do the big guys determine? Can I complain, and to whom? Etc.
Beyond standardisation: • implementations required? • proof of interoperability required • conformance testing	Indicate a more 'praxis-oriented' approach; crucial if products/services are to hit the market pretty soon.
Output	Description
Types of 'products'	Do an SSB's deliverables suit my needs? I do not always need a full blown standard, and may be prepared to swap consensus for speed.
Quantitative aspects: • standards output • # of implementations	Do they actually produce standards that are widely implemented? Indicates importance of output; if nobody implements the standards participation is hardly worth the effort.
Dissemination: • PAS submitter? • specifications for free?	Related to 'liaisons' above. Is an SSB prepared to bring its specifications into the public domain? And are they prepared to do it for free?
Follow-up activities: • standards maintenance • impact considered? • consistency checks in place?	How does an SSBs react to changes in technology/ requirements? And to errors/inaccuracies? Do they reflect on what they are doing? Are standards checked for consistency with others?

Table 2. Project stages and associated documents in the ISO/IEC process (taken from ISO, 2015).

Project Stage	Associated Document	
	Name	Abbreviation
Preliminary stage	Preliminary Work Item	PWI
Proposal stage	New Work Item Proposal ^a	NP
Preparatory stage	Working Draft(s) ^a	WD
Committee stage	Committee Draft(s) ^a	CD
Enquiry stage	Enquiry Draft ^b	ISO/DISIEC/CDV
Approval stage	Final Draft International Standard ^c	FDIS
Publication stage	International Standard	ISO, IEC or ISO/IEC
a	These stages may be omitted.	
b	Draft International Standard in ISO, committee draft for vote in IEC.	
c	May be omitted.	

standard cannot be implemented without infringing a patent this patent is called an SEP. Under the ‘Royalty Free’ (RF) regime licenses for such patents have to be granted for free⁵. Under a ‘(Fair), Reasonable and Non-Discriminatory’ (F)RAND regime the IPR holder may ask for licensing fees⁶. The SSO does not normally interfere with the negotiations between the IPR holder and the potential licensee(s). No generally accepted definition or algorithm for the calculation of FRAND exists and the courts are frequently called upon to settle disputes (see e.g. [Updegrove, 2013]).

The Standardization Process

In general, the standardization process should make sure that its outcome (i.e. the standards) meets the needs of as many groups of stakeholders as possible. To come at least close to this goal, the World Trade Organization (WTO) has defined a set of “... *principles and procedures that should be observed, when international standards ... are elaborated ...*” [WTO, 2015]. Specifically, these include transparency, openness, impartiality and consensus, effectiveness and relevance, coherence and to address the concerns of developing countries. Most major SSOs more or less observe these principles although formally they are only relevant for national and international SDOs.

Terminology, procedural and structural details may differ⁷, but all major SSOs have adopted a standardization process that is subdivided into several stages. Table 2 exemplary summarizes the stages of the ISO/IEC process. Once a new Work Item has been agreed upon, a Working Group (WG; either an existing one or a newly created one) is charged with the development of the associated standard. When the WG has agreed upon a draft specification the members of the parent Technical Committee or Subcommittee (TC/SC) need to reach consensus. Depending on the number and nature of comments received the specification may be returned to the originating WG for further elaboration. Eventually, a vote will be cast at TC/SC level. If the approval criteria (in terms of majority and number of negative votes) are not met a revised version will be produced. The latter two steps may differ between SSOs and may have several iterations.

It should once more be highlighted that virtually all SSOs follow a variation of this process⁸.

Not unlike the processes, the organizational structures of major SSOs are similar. In most cases both their technical work and their internal organization are hierarchically structured. Figures 4 and 5 exemplary show ISO’s governance and work structure, respectively.

Figure 4. ISO's governance structure

Figure 5. ISO's work structure

Typically, a TC covers a rather broad field. For example, ISO/IEC's Joint Technical Committee 1's (JTC 1) scope is 'Information Technology'. It is subdivided into 20 Subcommittees (SCs). Each Subcommittee, in turn, may comprise a number of Working Groups (WGs; more than 100 in total in JTC1). This is where the bulk of the actual technical work is done⁹. The more strategic decisions are normally taken at SC/TC level. This is also where the decisive voting is done.

MANAGING CORPORATE STANDARDIZATION

Standardization management refers to the set of activities a firm needs to perform in order to achieve its goal(s) in standards setting. That is, it needs to be clear about these goals in the first place. In many cases, standardization will be used as a tool to support a firm's business strategy in a given sector. To this end, standards setting activities and the business strategy need to be aligned.

Figure 6. Some factors that influence standards development (based on Jakobs, 2013).

Potential activities in standardization may range from simple intelligence gathering via pro-actively starting standardization initiatives to the foundation of a dedicated standards consortium to develop and promote standards for a particular field.

Once these corporate goals are clear, a number of factors need to be taken into account, including.

- The (potentially) relevant legal, moral, ethical, societal boundary conditions.

- The characteristics of the individual SSOs and the links that exist between them (see above). Here as well IPR issues will play a major role in many cases.
- The obvious allies and opponents that will also participate and their technical and strategic interests.
- Potential alliances that could be formed based on similar/complementing interests..
- The nature of the contributions to be made (e.g. technical, requirements, editorial).
- The content of the contributions.
- The size of the team, the roles and the necessary capabilities of its members.

The latter point is frequently ignored. However, at the end of the day standards are developed by a group of people who may cooperate or compete in a WG. These people's capabilities, backgrounds, views and agendas will to a considerable degree shape the final standard (see e.g. [Isaak, 2007], [Jakobs, 2011]). It should be noted that in addition to their technical expertise these people also need to be good communicators with a reasonable level of diplomatic and negotiation skills. It is, however, not always clear up-front whether or not they will actually act in the best interest of their respective employer [Jakobs, 2011]. Not least because of this uncertainty the selection of representatives with suitable expertise and experience and their briefing is a managerial issue whose importance should not be under-estimated.

Figure 6 summarizes and illustrates the different factors that need to be taken into account in corporate standardization management (without claiming completeness).

National Standardization Strategies

Not only firms have realized the importance of standards. Almost all industrialized nation states now have developed their own national standardization strategy¹⁰. Typically, standards are seen as important for the economy, policy making

and societal issues. A typical statement reads “*Standards are a fundamental building block for the economy and society*” [NSSF, 2003, p. 4]).

Almost all national strategies highlight the increasing globalization of markets and the resulting equally increasing need for globally valid, unique and accepted standards. At the same time, they also aim to provide a competitive advantage for the respective national firms and to strengthen the respective national position in the global market.

A number of other aspects may also be found in most national strategies. These include, for instance, the links between research, innovation and standardization. Along similar lines, they highlight the role of standards as a vehicle for the transport of innovations to the market as well as for the convergence of technologies (e.g. broadcasting, telecommunications and IT). The support of adequate education about standardization is another goal. This holds for both formal curricula and training on the job.

To achieve these goals, the need for an adequate national standardization infrastructure is stressed. This also includes the adaptation of current processes to shorter product life cycles and increasing consumer requirements. Specifically, the need for adequate (public) funding of the standardization infrastructure is also highlighted, not least in the light of the economic importance of standards.

Despite these similarities a number of differences between national strategies may also be identified. For one, the special needs and requirements of Small and Medium-sized Enterprises (SMEs) are only addressed in the strategies of the European countries. And while all strategies aim to improve the national performance in globalized markets the US strategy quite openly aims to ‘export’ its sector-based national standardization system, not least to counter the export of European technology and practices to other nations through the European standards processes. The Chinese strategy is the only one that explicitly highlights ICT. ‘Next Generation Information Technology Industry’ is the second of the 13 major areas iden-

tified where science and technology shall support the development of new technical standards. The support of R&D (Research and Development) for standardization is another focus of the strategy, an aspect the other strategies only touch upon.

FUTURE DIRECTIONS

In the past couple of years standardization has seen a development that may eventually change the whole standardization landscape – the mergers of formerly separate sectors. The – almost finished – integration of (tele)communication and information technology led to ICT. A next step – currently being taken – is the integration of ICT and broadcasting. IPTV and Internet Radio are well-known cases in point.

Such mergers of technologies will continue, and they are likely to do so on a broad scale. These emerging new technological fields will also be based on technical standards. Examples here would include, among others, Intelligent Transport Systems (ITS; ICT, transport telematics, traffic engineering), electric vehicles (ICT, automotive, power supply), e-health (ICT, medicine) and, perhaps ultimately, the Internet of Things (IoT) and Cyber-Physical Systems (CPSs; ICT and pretty much everything else).

These merging technologies represent a considerable problem for standards setting. They will require co-operation between standardization entities with very different cultures, from equally different backgrounds and with very different technology life cycles. On top of that, ICT in general, and specifically technologies like e-health and CPS, need to address issues of information security and safety and of trust. These aspects as well will need to be considered in the standardization process, adding yet another dimension of complexity. It remains to be seen if and how these problems will be addressed in practice.

CONCLUSION

Standards are crucially important, both economically and technically. This holds especially for the ICT sector, which simply would not function without globally accepted and implemented interoperability standards. Ongoing developments like ITS, e-health and the IoT, all of which require considerable interdisciplinary co-operation, will further increase the importance of standards and the underlying standardization processes.

KEY TERMS AND DEFINITIONS

Information and Communication Technology (ICT): Encompasses computer hardware and software as well as the communication networks necessary to process and transmit data.

Innovation: The implementation of a new or significantly improved product (good or service), process or new organizational method.

Intellectual Property Rights (IPR): IPR is the legal right granted with the aim to protect a creation of the intellect. These include e.g. patents, trademarks and copyright.

Standard: Document, established by consensus and approved by a recognized body, that provides, for common and repeated use, rules, guidelines or characteristics for activities or their

results, aimed at the achievement of the optimum degree of order in a given context.

Standardization: The process through which a standard is developed.

Standards Setting Organization: An organization that provides a platform for the development of standards.

World Trade Organization (WTO): The WTO deals with the global rules of trade between nations. Its main function is to ensure that trade flows as smoothly, predictably and freely as possible.

ENDNOTES

- ¹ In short, according to [ISO, 2015] consensus means a general agreement, characterized by the absence of sustained opposition to substantial issues. Consensus need not imply unanimity.
- ² ITU is a United Nations agency for information and communication technology issues.
- ³ This term is used to denote both formal SDOs and private standards consortia.
- ⁴ <http://www.3gpp.org/>.
- ⁵ The World Wide Web Consortium applies the RF regime.
- ⁶ All SDOs and most consortia apply the (F) RAND regime.
- ⁷ In the following, ISO terminology will exemplary be used.
- ⁸ See [Morales-Trujillo et al., 2015] for a detailed description of a process leading to a de-facto standard.
- ⁹ Depending on the SSO's bylaws WG members either act in a personal capacity or represent their employer or country, respectively.
- ¹⁰ A compilation of such national strategies may be found through <http://www.strategicstandards.com/Perspectives.html>.

Immersing People in Scientific Knowledge and Technological Innovation Through Disney's Use of Installation Art

Jonathan Lillie

Loyola University Maryland, USA

Michelle Jones-Lillie

Lillie Pad Studios, USA

INTRODUCTION

This chapter uses Disney's extremely successful exhibits at the 1964-65 New York World's Fair as iconic examples of art installations designed to provide strong experiences of scientific progress and technological innovation. The chapter therefore explores how Disney and installation artists have used this form to create immersive, memorable experiences for audiences. The goal is to identify methods for using installation art to convey scientific knowledge to general audiences to foster greater understanding and inspire future generations toward scientific and technological discovery.

When Walt Disney began to sketch out his plans for Disneyland, which opened in 1955, he was explicit in this desire to bring the same narrative craft to rides and exhibits that he demanded of his feature films. He wanted visitors to (actually) step inside, immerse themselves in the story and experience the wonder and emotional connection directly. While the Disneyland and World's Fair exhibits are certainly not the first examples of the construction of large-scale, immersive narrative experiences, they have been extremely influential in the areas of art, education and culture. At the 1964-65 fair in New York, Walt Disney wanted to demonstrate the vast improvement in installation/dark ride technology over the 1939 World's Fair (also in New York) and its influential future-gazing exhibits such as GM's "Futurama." In later

years the Disney Company, groups of artists, and institutions such as museums have drawn on the methods used by these iconic exhibits to develop installations to convey concepts and trends in science and technology.

Disney designed and built four installation exhibits for the 1964-65 fair: Ford's "Magic Skyway"; "The Carousel of Progress" for General Electric's Progressland Pavilion; "Great Moments with Mr. Lincoln" for the State of Illinois; and "It's a Small World" co-sponsored by Pepsi and UNICEF. The narrative craft of exhibits such as Carousel of Progress (Figure 1) and the Magic Skyway (Figures 2 and 3) are compared below to works within the genre of installation art, which has developed greatly since the 1960s. Similar to Disney, many artists have deployed immersive installation art exhibits to envelop audiences in a detailed aesthetic and conceptual narrative. Some artists, as well as educational institutions, have used experiential installations for addressing or presenting scientific concepts, and much potential exist for further work in this direction.

HISTORICAL BACKGROUND AND LITERATURE REVIEW

The 1950s and 1960s were vital for the development of installation art. Installation was one of several anti-commodity forms such as conceptual art, performance and body art, earth works, and

DOI: 10.4018/978-1-5225-2255-3.ch407

Figure 1. “Father,” dog, and electric oven from the Walt Disney World revised version of the Carousel show (2006, public domain, photo by SteamFan available on Wikipedia)

new forms of sculpture, which emerged in these decades (Morse, 1998, p. 4). However the birth of the genre is often traced back to the surrealist exhibits held in Paris in 1938, 1957, 1959 and in New York in 1942, which inspired the contemporary “Art Installation movement” insofar as the artists desire to display their artworks according to their own aesthetics rather than allowing a museum curator to take on that task (thus, defining the exhibition of the collection of artworks as an integral element of the artwork as a whole). The first of these was the 1938 *Exposition Internationale du Surréalisme*, a surrealist exhibition held in Paris that included Salvador Dali’s installation “Rain Taxi” (Tomkins, 1996, p. 364). In the 1960s and 70s installation art was certainly explored, however the occurrences were sporadic and did not truly reach the height of its label as an artistic movement until the 1990s (Bishop, 2005, p. 8). In the 1980s installation art began making its way to the forefront in major international exhibitions such as *The Venice Biennale*, *Sao Paulo Biennial*, and *the Skulptur Projekte, Munster*, as a way to fill large architectural or industrial spaces with a sensorial experience aiming to leave guests with a more tangible memory of the exhibition. Increasingly,

more and more post-1960’s art venues sought to exhibit installation art as an outcome. Currently, Installation Art is the backbone of many international biennials and triennials for its ability to completely immerse the guests in the art and alter the consciousness of the guests through sensory perception (Bishop, 2005, p. 37).

The Disney exhibits at the fair are examples of installation art in several aspects. First, as opposed to more long-standing forms of two-dimensional art, installations must, of course, be installed by the artist(s), typically in a prepared space. Often in more immersive works the boundaries of the space, such as interior walls, have been modified to the specific needs of the piece, transforming it into a new “environment.” Following the surrealist expositions of the 1930s and 40s, the next important development of the genre emerged with the experiential “environments” and “happenings” created in the 1960s by artists such as Allan Kaprow, who were reacting against the commercial boom of Abstract Expressionist paintings in European and American galleries (Bishop, 2005, p. 23). As opposed to Disney’s commercial engineering approach,¹ the spaces for these Kaprow’s environments tended to either be disused

Figure 2. The Magic Skyway (© 1965. With permission from the Collections of The Henry Ford)

spaces such as abandoned warehouses and caves, or galleries extensively altered by the artists.

The fair exhibits are also installations in that they accomplished “the actual construction of a passage for bodies or figures in space and time” (Morse, 1998, p. 154). As art historian Margaret Morse describes, the character of installation and the materials inside the installation are “meaningful within the whole pattern of orientations and constraints on the passage of either the body of the visitor or of conceptual figures through various modes of manifestation—pictorial, sculptural, kinesthetic, aural, and linguistic” (p. 154). Indeed, the Disney installations at the fair took advantage of all of these ways to engage visitors. Disney developed several modes of manifestation to achieve this vision for the Magic Skyway, which took passengers in modified Mustang convertibles on a journey of ‘human progress’ from the invention of speech by early humans to techno-cities of the future. “What we want to provide guests at the Ford Pavilion is an entirely original experience, something no one has ever seen or done before,” Walt promised in his sales pitch to Ford. “It could never happen in real life, but we can achieve the

illusion by creating an adventure so realistic that visitors will feel they have lived through a wonderful, once-in-a-lifetime experience” (Ford Times, December 1963). Of particular note are the sculptural and kinesthetic techniques used in the Skyway and Carousel. The Skyway (Figure 3) first allowed visitors a “stunning” view of the fairgrounds before traveling back to “the dawn of life.” It was here that audio-animatronic dinosaur sculptures battled in a foggy prehistoric landscape. The next scenes presented “cavemen” in comic scenes inventing speech, writing, and the wheel (Figure 3). These sculptures moved by a pneumatic technology developed a few years earlier for the jungle cruise in Disneyland. GE’s funding of the Carousel (as well as the money for the Lincoln robot for the Illinois pavilion) allowed Disney’s engineers to take audio animatronics to the next level to create the “lifelike” stereotypical white, mid-western, American family (Figure 1). The heavy reliance on audio animatronics, aside from practical considerations, contributed to a sense of technological wonderment and authenticity. These mechanical bodies in movement shared the same space with the slowly moving visitors. And

the kinesthetic aspect of being moved through the exhibit was just as important to the visitors' experience as the robot characters were. Both the Skyway and Carousel² were thematically based on a linear movement through time, witnessing a segment of human history.

Compared to most installation artwork the Disney installations were over-proscribed and constraining to visitors, more like the classic cinematic experience of being shunted to a dark seat to observe with an omniscient narrator to guide you through the story (the exhibits used narrator voices, music, and sound effects). Morse explains how the theater and film can be explored through Plato's "Simile of the Cave" where the spectator is divided from the realm to be contemplated. In the cave, "the machinery that creates the vision of another world is largely hidden, allowing the immobilized spectator to sink into an impression of its reality with horror or delight but without danger from the world on view," Morse notes.³

It is here that we can find perhaps the greatest difference between the Disney exhibits at the fair and installation art. What Disney hoped to learn

how to perfect at the fair and new rides at Disneyland was the immersification of the modern film. Creating a space where visitors are able to actually go inside the narrative with their bodies, not just their minds, as the cinema experience seems to privileged. Most installation art, on the other hand, try to force visitors to be mindful and critical of where they are, what they are doing, and what is being done to them. Many art historians (Hawkins, 2010; Morris, 1998) see immersive installation art as particularly useful in drawing attention to the fact that cognition is a product of embodied experience. For example, artist Natalie McKeever's installation "Internal Worlds" (2013, Figure 4) immerses the body in a technological apparatus to not only make the visitor more aware of her or his own body – visitors see and here their own biorhythm data in real time – but also of their bodily existence in a technology saturated society. This installation is "an ontological study of humans' body-mediated perception in a world" (Lillie, 2014) where perception is increasingly mediated through ubiquitous information and communication technology.

IMMERSIVE NARRATIVE

V. IMMERSIVE PLAY

"The underlying premise of installation appears to be that the audiovisual experience supplemented kinesthetically can be a kind of learning not with the mind alone, but with the body itself," writes Morse (1998, p. 158). Certainly this description can be applied to Disney's installations. The fair exhibits were undoubtedly so powerful due to how the visitors' bodies were moved through a *narrative*. Narratology scholar Gerald Prince notes that the word narrative has emerged from the Latin *gnarus*, which is translated to "knowing" or "acquainted with." *Gnārus* comes from the Indo-European root *gnā*, which means "to know." Narrative therefore "is a particular mode of knowledge," Prince concludes. "It does not merely reflect what happens; it discovers and invents what can happen. It does not simply record events; it constitutes and interprets them as meaningful parts of meaningful wholes, whether the latter are situations, practices, persons, or societies" (Prince, 2000, p. 129). With Disney's use of installation, rides and exhibits were, and still are, most often

used to convey narratives about technological progress (e.g., many of the original and current features at the Epcot Center theme park in Florida, USA). The careful crafting⁴ of narrative invites cognition, decoding and often dominant readings. Knowledge presentation of any kind faces the same challenge as any message created for consumption, finding a successful way to convey a concept. Disney solution to this conundrum is found in its devotion to the complete storytelling process: every aspect of the narrative and how to tell it was, and still is, absolute. Whereas Disney's exhibits tried very hard to encourage audiences to connect pro-social emotions to specific concepts, most installation artists design their works to be open to a wide range of interpretations. Both Disney and most installation artists, however, strive also to evoke an emotional reaction.

The installation artist leaves the location once set up is complete, leaving the visitor to perform the work on her own, or at the same time as other visitors. Rarely are installations as scripted and narrative driven as the Disney exhibits,⁵ but media scholars recognize that with forms such as television and film, the mind of the viewer is

usually highly active, making meaning from what they see and hear. Disney's exhibitions displayed masterful use of textual references, often nostalgia, for visitors' minds to decode, often with an emotional response. Whether the classic T-rex vs. Stegosaurus fight and caveman antics of the Skyway, the long-suffering livingroom patriarch in his armchair of the Carousel, or the austere, inspiring audio-animatronic President Lincoln of the Illinois pavilion, visitors are able to access the many textual references to American culture and history so that the experience seems bigger and more significant than just a tour through a large aluminum building. And audiences were also always primed in the pavilion pre-shows for the amazement that they were about to experience. In contrast, installation artists such as Ilya Kabakov often arrange related objects in a room, or series of room, in an attempt to tell a story that is very much open to visitors' interpretations (*see* Bishop, 2005, p. 15-16, for a description of Kabakov's narrative installations).

Unlike the scripted, controlled experience that Disney preferred, most installation art is often predicated on letting, or even forcing, the audience to *play*, in other words the journey through the narrative is often a choose-your-own adventure of sorts. While the artist guides the audience there is much more room for a wide variety of experiences and interpretations. As in other areas of the arts, installation artists' uptake of critical/postmodern theory (more Foucault [1977], Baudrillard [1981], and Barthes [1957] in this discipline than Jameson [1991]) understands that no reading of a text can be determined, and in fact that may not be desirable. Although almost all installation art is conceptually grounded, immersive installations are often designed to be experienced through the full range of human senses, but also upping the cognitive ante by encouraging audiences to actively think about and critically analyze what they are experiencing and feeling. Therefore, installation art audiences are often left feeling that they made their own conclusions based on their ability to think critically as oppose to being swept through an experiential

journey merely to be entertained. The relationship between the artist and the audience seems agreed to be about reaching an intellectual enlightenment of a sort, which of course is an admirable goal for many undertakings of scientific knowledge presentation, especially in educational settings. Educational destinations such as zoos, aquariums, and science centers have for several decades continued to increase the number and diversity of interactive exhibits (Allen, 2004), acknowledging that there are many ways to convey knowledge and you never know which method will end up connecting with which visitor.

The importance for interactivity, some call it "play," for installation artists is similar to the importance of visitor exploration and discovery for immersive installation artists and science or cultural museums alike. Sue Allen, the director of visitor research and evaluation at the Exploratorium in San Francisco, acknowledges that the self-guided exploration that makes science museums so fun and novel also makes them difficult to design for learning. "On the exhibit floor there is no accountability, no curriculum, no teachers to enforce concentration, no experienced guide to interpret and give significance to the vast amounts of stimulus and information presented," she writes. "Without restrictions, visitors have complete freedom to follow their interests and impulses as they move through a public space packed with exhibits all vying for attention" (2004, p. 18). Immersive installations, however, generally do not suffer from this problem, since they are typically a single exhibit focused on one particular experience and concept.

INSTALLATION FOR KNOWLEDGE PRESENTATION

In a reputable volume on representation in scientific practice Lorraine Daston reminds us that the "specter of the perfect copy still haunts the history of science, despite the best efforts of scientists and artists to explain that the most faithful rendering

is often not one that could be mistaken for the original” (Daston, 2014, p. 319). Presentations or demonstrations of scientific concepts will often fall short when they do not make sense to lay audiences and cannot address the “bigger picture” or contexts. Of course all such endeavors must be simulations of a sort, and there is a danger in the possibility that audiences will believe that simulations are indeed exact replications. Many children left the Magic Skyway feeling they had glimpsed a close approximation of what dinosaurs and “cavemen” were actually like; some visitors watching the Abraham Lincoln robot give its speech thought it was a human actor. And the Carousel purported to tell a truism story of the history of the American home. On the other hand, narrative storytelling is one of the most fundamental forms of knowledge acquisition for our species, the other being direct experience. But both of these are considered flawed by the paradigm of objectivity. This is perhaps one of the reasons science loves “facts” in the form of numbers, stats, and equations born out by experimentation and/or detailed observation. They seem more like truth, but we need language to convey them. Also, the things such facts are telling about are typically so far abstracted from the reader of such knowledge that it is difficult to place it in context, to “make sense” of it in the context of our everyday lives. Which is where storytelling, narrative, comes in. Can you imagine if Disney’s follow up to *Frozen* were a strong message on the need for every person and community to act to combat global warming? But of course any heavy-handed message would detract from the narrative and would therefore the concept would be severely lightened and simplified to make it more digestible for multiple publics and corporate sponsors. Installation art on the other hand is well suited to presenting scientific knowledge, acknowledging and desiring for the narrative to be highly subjective but also emotionally powerful.

Part of the power in the Disney rides was that they were literally and figuratively a journey through the narrative. In the Carousel of Progress and Magic Skyway the forced movement of the

audience was central to experiencing the concept of the movement through time and history. Yet the experiential possibilities were constrained and forced by the design of the immersive narrative apparatus. Interactive scientific exhibits are similarly constrained by the apparatus design. A web-based science exhibit is experienced and constrained by the technology: keyboard, screen, the possible modes of user interaction programmed into the webpage and again limited by what current technologies can enable. Regional science museums and discovery centers on the other hand are place-based with open-architectures, built to engage children’s sense of play and exploration. Typically many individual exhibits inside these centers use methods of knowledge presentation, but the overall purpose is not merely rote learning of scientific facts and concepts, but perhaps more vital, cultivating a love of learning about the world and a desire to know more. In some respects many immersive art installations are more like these science centers for kids than the Disney exhibits and rides. Morse notes that we “lack the vocabulary for kinesthetic ‘insights,’ for learning at the level of the body ego and its orientation in space. Perhaps such learning principles might be considered ‘Deweyian,’ a ‘figuring within’ as opposed to the ‘reading’ of literature or the ‘imagining’ of pictorial art” (Morse, 1998, p. 153). However educational institutions in sciences, whether engineering, medicine, chemistry, etc., have long understood that knowledge as it is desired to be applied must be learned in part through experience. For an example of installation used in science education, consider “the Giant Heart” (Figure 5) exhibit at the Franklin Institute in Philadelphia, where visitors walk through the gallery-sized heart installation and learn about the mechanics of the human body.

CONCLUSION

Although the Disney model of dark-ride installations are by many measurements highly success-

Figure 5. “The Giant Heart” at the Franklin Institute (© 2010 Cary Whitt. Used with permission)

ful, there are also many reasons why scientists or educational institutions might not go down that path to presenting knowledge with a strict narrative script for large audiences. First of all: It takes a lot of money! Walt Disney was mainly interested in participating in the 1964-65 fair because the company did not have the funds to support all the research and development needed to expand Disneyland with high-tech dark rides. He needed the fair's rich corporate sponsors for that. Similarly, like large science studies, large installations typically require funding. Certainly funded installations that present scientific knowledge are to be applauded not shunned, but the trick is to allow artists to use their conceptual knowledge and skills and not force perceived modes of entertainment into the installation, which in fact might close down rather than open up visitors' abilities to critically engage. Second, when a highly narrative immersive installation is intended to be at least in part entertaining, the tendency will usually be to eschew complex facts for amusement and narrative simplicity/coherence. While science and history museums are important institutions for experiential education, where installation is often

one form of knowledge presentation, such venues are often burdened with many other tasks – such as boosting attendance, growing endowments, developing age-appropriate curricula for school fieldtrips and the like (*see* Silberman's, 2005, critique of museums).

Installation can be a powerful tool for moving people. They may move people physically and emotionally, as the Disney exhibits at the fair, or they may move people to critical thinking, or merely move people out of their comfort zone. Certainly, for many artists, one of the reasons for making art is to compel people to both have an emotional reaction to a work but also to think critically. Yet this is also a dual purpose for the making and conveying of scientific knowledge. The title of the popular web/social media curator, “I Fucking Love Science” is very illustrative of this point. Of course, unlike Disney, where the desired emotional responses are positive (wonder, amusement, etc.) some of the most powerful installations hope to invoke unexpected, disjointed feelings from visitors, provoking them to reflect on how they are feeling and why. A variety of studies in the biological sciences have shown that

emotional experiences are typically better stored in memory (see Bower, 1992; Canli et al., 2000; Christianson, 1992). For example, a recent study of visitors to a wildlife exhibit found that four months later visitors recalled emotional responses much more than factual information and that they connected these emotions to positive changes in their pro-conservation attitudes and behaviors (Ballantyne, Packer, & Sutherland, 2011). This could be the reason so many visitors to the 1964-65 New York fair report fond and detailed memories of the Disney installations even decades later (Anderson, 1995). While Disney wanted to create powerful, pro-social entertainment, for many installation artists, however, the purpose of their artwork is to provide visitors with experiences that are powerful because they are out of the ordinary – sometimes unsettling, other times mesmerizing – but typically using an immersive, multiple media approach to impart such feelings.

FUTURE RESEARCH DIRECTIONS

Conveying scientific knowledge and technological innovation faces the same challenge as any message created for public consumption: finding ways to convey a concept. Disney as well as many installation artists realized that conveying the message can be a much more powerful experience when audiences are compelled to feel. Cognition is never merely conveying of information. Human cognition might be computer like in some respects, but as phenomenologists have realized for decades information must be routed through the whole body-as-apparatus to go through the process. Disney's method for this was cinematic, and thus the company's devotion to the complete storytelling process, every aspect of the narrative and how to tell it, was absolute. Artists on the other hand take many different approaches to developing a 'structure of feeling' through installation. The majority of colleges and universities that offer degree programs in art offer courses in

Installation Art. And it so happens that colleges and universities are at the forefront of science and technology discovery and education. Therefore collaboration between Art departments/faculty/students and their counterparts in the Sciences would be the logical vehicle for developing installations that convey new science and/or technology concepts. Such cross disciplinary ventures are likely to be supported by educational institutions that are increasingly trying to get students to make connections among their different disciplines of study. Furthermore these collaborations can be flashpoints for developing partnerships with local tech industries, science centers, and museums.

KEY TERMS AND DEFINITIONS

1964-1965 New York World's Fair: Between April 22, 1964 and October 17, 1965 fifty-one million people visited the New York World's Fair held at Flushing Meadow in Queens, New York, on the site of the 1939 World's Fair. Due to a stipulation that no nation can host a World's Fair more than once a decade and that an official World's Fair was held in Seattle in 1962, the New York Fair did not enjoy the official sanction of the Bureau of International Expositions.

Dark Ride: A “dark ride” is the term often used to describe large indoor installations produced for the purpose of entertainment at theme parks such as Disneyland. They tend to be heavily immersive and themed environments. They are called by other names as well, such as “ghost train” in the UK and Australia.

Disney, Walt: Walt E. Disney (born December 5, 1901 – died December 15, 1966) is a famous American media pioneer. The Walt Disney Company, founded by Walt in 1923, is best known for its animated fantasy feature films, theme parks, and television channels ABC, ESPN and the family of Disney channels catering to children and teens.

Installation Art: An art movement or genre based on three-dimensional work. It was not considered a true art movement until the 1980s, but has roots in surrealism exhibitions of the 1930 and 40s. Most installation artwork comprises multiple objects, multiple media, and takes up a whole room or many rooms in a gallery or venue.

Kaprow, Allan: Kaprow (1927–2006) was an American artist known for organizing art exhibitions in the 1950s and 60s that he termed “environments” due to the artists’ altering of the art venues combined with thematic performances.

Narrative: A narrative is simply a story or version of events communicated through language. Scholars in many disciplines including English, media studies, linguistics, cultural theory, and anthropology have studied how humans communicate and form communities using different forms of narrative. Since installations use many pieces of art, they can be used together to create a narrative of sorts.

ENDNOTES

- ¹ For the fair Disney's architects and “imagineers” drew up specs for the buildings that had to be constructed to house its feature exhibits. Despite this large-format construction, however, all four exhibits along with almost all of the other structures associated with the fair were torn down. The vast majority of installation artwork is only temporarily installed in a location. More successful and well-funded installations may bounce among museums and galleries as traveling exhibits. The Carousel, Small World and Lincoln robot were all later installed as slightly different versions in Disneyland and later duplicated (and again slightly revised) more than a decade later for Disney World in Florida.
- ² For the Carousel Disney engineers proposed and developed the first revolving audience

theater: a “doughnut on railroad wheels” containing six compartmentalized sets of seats revolved around the center that contained six stages allowing a 3,900 people per hour capacity (Anderson, 1995, p. 53). The stages showed the animatronic family enjoying state of the art home electronics from the 1890s, 1920s, 1940s, and late 1960s. The central concept of technological progress was literally felt as the whole group of seats moved as one scene ended to the next scene that represented ideal middle-class domestic life decades later.

³ Morse continues: “Cinema spectators immobilized in darkness were like the prisoners in Plato’s Cave, but they are not held in place by chains but by machines of desire, enjoying the impression of mastery over an imaginary world” (Morse, 1998, p. 156-157; See Morse for a discussion of film theory’s critique of Rene Descartes’s [hence “Cartesian”] arguments about human experience). Critical theories have drawn particular attention to how to the modern era of film has been dominated by Cartesian narratives/design, where bodies are placed, immobile, in a black box to observe the neat, manufactured realities on the other side of the screen.

⁴ The Disney exhibits were successful due to their rigid devotion to narrative craft. The use of technology made the exhibits seem to come to life, enhanced visitors’ sense of wonder and evoked a positive emotional response. Thus the techno-enabled narratives were made it more likely that these experiences would imprint into memory. And the rides were designed to enable as many people as possible to have a similar pro-social narrative experience. The company was still so geared toward cinematic narrative construction in the 1950s and 60s that the lead project managers for the fair exhibits

and Disneyland were called “art directors.”

Perhaps the fair exhibit with the most long-term success and impact was “It’s a Small World,” which – 50 years later – is currently in operation in all six major Disney theme parks around the globe. Although “Walt’s little boat ride” was a tour through 26 world cultures, he wanted a strong, consistent design style to drive the narrative. Mary Blair, who provided concept art for recent Disney films including *Cinderella*, *Alice in Wonderland* (1951) and *Peter Pan* (1953) was brought in to provide styling themes for the ride including the child sculptures, faux buildings and landscaping, and facades inside and outside the building that housed the ride. Similar to Disney’s feature films, catchy songs were also central to the narratives of the Carousel (“It’s a Great Big Beautiful Tomorrow”) and Small World.

⁵ For the Disney exhibits most non-scripted physical interaction between visitors and the exhibits were not desired due to the need for high per-hour capacity. But such interactivity was also viewed as a detractor from the carefully crafted narrative. Ford Motor managers wanted Ford salesmen to act the role of chauffeurs in the Skyway mustangs, which they thought would certainly result in increased sales of their newest model (the mustang’s official debut date was the opening day of the fair). But Walt personally talked them out of this plan, saying it would detract from the wondrous experience that the Skyway would impart (Anderson, 1995, p. 55). Disney’s devotion to cinematic narrative was so complete that the instances when the narrative was interrupted by temporary mechanical glitches, the extent to which the experience is manufactured and constraining becomes quickly evident.

INTRODUCTION

Over the past twenty years, technologies using microelectronics for collection, storage, processing, retrieval, transmission, and presentation of data, texts, images, and sound, collectively known as ICT have completely changed all people's activities. The rapid proliferation of ICT and their impact on all spheres of modern life (see Ahmad et al. [2004]) – production processes, the interaction of individuals and organisations with public authorities, the development of social infrastructure, and privacy issues – has stimulated the interest to statistical analysis of the ICT sector's prospects at the national and regional levels. Influence of ICT led to emergence of a new socioeconomic configuration commonly referred to as "Information Society".

BACKGROUND

An Information Society is usually understood as a society that makes extensive use of information networks and technologies, produces large quantities of ICT goods and services, and has a diversified content industry. Both theoretical and practical issues related to measuring different aspect of Information Society has been increasingly addressed by many authors during the last 20 years (see for example Blank, Groselj [2014];

Dolničar et al. [2014]; Billon et al. [2016]). The key three thematic "pillars" related to the Information Society are as follows (Figure 1):

- **ICT Sector and the Supply of ICT:** Which industries it includes, how important they are for the national economy, how many enterprises are involved and how many persons are employed, which types of products and services are produced, and what is the total turnover?
- **Technical Infrastructure:** Including the penetration rates of landline and mobile telephone networks, the number of computers per inhabitant and the number of Internet connections (whether or not a country is ready to become an information-based society).
- **ICT Demand:** Which enterprises and individuals are using ICT products and services? Which technologies are being used, and why? What barriers hamper a country's integration in the global Information Society?

Despite the fact that the Information Society Statistics is a relatively new area, international organisations have already adopted a set of harmonized measurement standards and allied indicators, and put together the necessary methodological foundations. The Organisation for Economic Co-

operation and Development (OECD), the Statistical Office of the European Union (Eurostat), the International Telecommunication Union (ITU), and the United Nations Conference on Trade and Development (UNCTAD), the Partnership on Measuring ICT for Development (Partnership) play the leading role in this effort (Table 1).

Statistical standards are developed by international organisations' working groups in cooperation with national statistical services, in particular: the OECD Working Party on Measurement and Analysis of the Digital Economy, the Eurostat Working Group on Information Society Statistics, the ITU Expert Group on Telecom/ICT Indicators, the ITU Expert Group on ICT Household Indicators. Use of international statistical standards is usually voluntary; however, to ensure full-scale participation in international data exchanges, and to be able to assess the country's prospects in the

context of global trends, most nations follow the international recommendations on measuring ICT.

INTERNATIONAL STANDARDS FOR THE INFORMATION SOCIETY STATISTICS

Information Society Statistics is one of the newest branches of social and economic statistics aimed at studying all aspects of activities related to production of ICT goods and services, proliferation and usage of ICT in the economy, social and public sectors, and private life (HSE, 2014).

Information Society Statistics has the following objectives:

- Regular collecting and processing relevant data;
- Studying ICT development trends, assessing policies aimed at supporting further development of the Information Society;
- Conducting international comparisons, calculating international rankings;
- Providing reliable, and comprehensive data to users;
- Publishing working papers, manuals, outlooks, data books and databases.

The main international body developing relevant methodologies, from the very beginning, has been the OECD. Several issues of the OECD Guide to Measuring the Information Society were published, summarising the experience accumulated over many years of studies (2005, 2009, the latest edition – 2011). The 2011 Guide presents basic concepts, definitions, and classifications, and includes recommendations on collecting internationally compatible statistical data in the following areas:

- **The Information Society:** The conceptual model in statistical terms;
- **ICT Products:** Definitions and classifications relating to ICT goods and services, measurement of international trade in ICT goods, prices and quality of ICT products;
- **ICT Infrastructure:** Access, quality, investments, tariffs;
- **ICT Supply:** The ICT sector and its impact, other suppliers of ICT, ICT patenting activity;
- **ICT Demand by Businesses:** The model survey of ICT usage by businesses includes proposed statistical standards for e-business and e-commerce, ICT investment and expenditure by business, and the economic impacts of ICT investment and use;
- **ICT Demand by Households and Individuals:** The model survey of ICT access and usage by households and individuals; includes a discussion of e-commerce

and the social and economic impacts of ICT use by households and individuals;

- **Content and Media Sector:** Statistical issues related to information and electronic content, and more recent work on defining the content and media sector and its products;
- **The International Scene and the Road Ahead:** Overview of the international activities on measuring ICT, and future challenges (OECD, 2011).

Currently most of the countries and many international organisations apply, though to a different extent, the OECD-proposed methodological approaches to statistical surveys and analyses of the ICT sphere.

Basic OECD statistical standards for measuring ICT usage are harmonised with Eurostat statistical methodology and data collection practices adopted by the EU countries (*Eurostat, 2016a*). In its turn, the European experience prompted further development of the OECD's and other international organisations' activities in this area.

The ITU provides definitions, which serve a basis for developing ICT infrastructure indicators. Its guide (ITU, 2011) is a key reference document for collection of internationally compatible indicators on telecommunications/ICT based on administrative sources (i.e. supply-side data mainly provided by operators). Due to the rapid development of the telecommunications sector, indicators have to be regularly adjusted. The impressive growth and transformation of the mobile communications and Internet sectors made it necessary to review the existing definitions. The current version of the Handbook includes definitions and methodological clarifications for 81 internationally agreed indicators and corresponding sub-indicators, discussed by the ITU. It fully reflects the main aspects of monitoring development of infrastructure: landline and mobile telephone communications, Internet, tariffs for communication services, investments in telecommunications, and other relevant indicators.

UNCTAD's activities include collecting and analysing national statistics, as well as providing consulting and training services to countries willing to produce internationally compatible ICT indicators. The Manual for the Production of Statistics on the Information Economy (UNCTAD, 2009) contains recommendations for national statistical offices on methodological and practical aspects of statistical surveys of ICT development and application in the economy. It includes definitions, data sources, and methodologies for calculating important indicators, questionnaires, and analysis of methodological issues commonly arising in the course of relevant statistical surveys, together with suggestions on dissemination of statistical information.

The international institutes promotes international comparability of indicators through them outreach activities. The Partnership on Measuring ICT for Development is a good example (Partnership, 2010).

The main activities of Partnership are developing and maintaining a Core List of ICT Indicators. Other activities include compilation and dissemination of ICT data, and provision of technical assistance to help statistical agencies collect data for the Core List of ICT Indicators. The latest version of the Core List is based on a supply/demand conceptual model of the Information Society and covers the following areas: ICT infrastructure and access; ICT access and use by households and individuals; ICT access and use by enterprises, ICT sector and trade in ICT goods; ICT in education; ICT in government (UN, 2016).

Now we observe explosive growth of online economic activities including Internet access provision and Internet-based services. So a new direction of the measurement activities is developed – the study of the contribution of Internet economy to GDP. The international studies can be classified to the following criteria: the direct impact of the Internet on the economy (BCG, 2014; McKinsey, 2011; Bakshi, 2016), indirect economic impact of the Internet (Stiglitz., Sen,

Fitoussi, 2009; BCG, 2010), and its impact on the social sphere (OECD, 2013; Shah, Kwak, Holbert, 2011; Morton, 2006; Greenstein, McDevitt, 2011).

INDICATORS OF ICT AND CONTENT-RELATED ACTIVITIES

All ICT and content-related activities (information economy) are divided into two sectors: the ICT sector and the Content and Media sector.

The central aspect of a statistical study of the ICT sector is identifying the ICT-related activities (industries), and defining of goods and services produced in this area. The OECD definition of the ICT sector is based on the UN International Standard Industrial Classification (ISIC).

The definition of the ICT sector has been updated a few times. The latest was in line with adoption of the modified ISIC Rev. 4 and introduced as an official alternative analytical aggregation. Now the activities (industries) in the ICT sector are grouped into ICT manufacturing industries, ICT trade industries and ICT services industries. Their list which complies with the above definition contains the following positions:

ICT Manufacturing Industries

- Manufacture of electronic components and boards;
- Manufacture of computers and peripheral equipment;
- Manufacture of communication equipment;
- Manufacture of consumer electronics;
- Manufacture of magnetic and optical media.

ICT Trade Industries

- Wholesale of computers, computer peripheral equipment and software;
- Wholesale of electronic and telecommunications equipment and parts.

ICT Service Industries

- Software publishing;
- Telecommunications, included Wired telecommunications activities, Wireless telecommunications activities, Satellite telecommunications activities, and Other telecommunications activities;
- Computer programming, consultancy and related activities, included Computer programming activities, Computer consultancy and computer facilities management activities, and Other information technology and computer service activities;
- Data processing, hosting and related activities; web portals, included Data processing, hosting and related activities, and Web portals;
- Repair of computers and communication equipment, included Repair of computers and peripheral equipment, and Repair of communication equipment (UN, 2008).

Design of the Classification of ICT products used the same principles. ICT product classification enables statistical agencies to produce two types of data: about production, based on the Central Product Classification (CPC), and about imports (exports) of relevant products, based on the Harmonised System (HS).

In addition to the ICT product classification, there is an obvious need for a harmonised classification of ICT services. The services classification became possible, based on the new CPC Ver. 2 (OECD, 2011), which provided a detailed structure of the CPC Ver. 2 subclasses linking them with the ISIC Rev. 4 and HS 2007.

An internationally agreed definition of the Content and Media sector (comprising organisations whose economic activities involve production, publication, and/or dissemination of content) was developed in 2007–2008 on the initiative of the OECD, based on the ISIC Rev. 4. The sector covered the following industries:

- Publishing of books, periodicals and other publishing activities, included Book publishing, Publishing of directories and mailing lists, Publishing of newspapers, journals and periodicals, and Other publishing activities;
- Motion picture, video and television programme activities, included Motion picture, video and television programme production activities; Motion picture, video and television programme post-production activities, Motion picture, video and television programme distribution activities, and Motion picture projection activities;
- Sound recording and music publishing activities;
- Programming and broadcasting activities, included Radio broadcasting, and Television programming and broadcasting activities;
- Other information service activities, included News agency activities, and Other information service activities n.e.c. (UN, 2008).

Today, core indicators on ICT sector and Content and Media sector are as follows: value added, share in total value added, employment, share in total employment.

INDICATORS OF ICT INFRASTRUCTURE

Statistical surveys of ICT infrastructure describe results of telecommunication activity (as a segment of the ICT sector), and of broadcasting organisations as a segment of the Content and Media sector. These include communication services output, revenues, and number of personnel.

ICT infrastructure indicators include: access to the Internet, telephone, telegraph, satellite communications; radio communications; volume of Internet and mobile traffic. These include numbers

of Internet users with mobile, fixed, and broadband access, mobile subscribers, etc.

Indicators measuring accessibility of communication services, such as tariffs for local landline telephone calls, mobile communications, and landline broadband Internet access, also play an important role.

Due to convergence of networks, services, and devices, indicators on ICT infrastructure now include television indicators. Development of the television segment is measured by availability of mandatory TV channels and the population's coverage by digital on-air and cable TV broadcasting.

These indicators are important not only to measure the level of ICT availability, their use for the estimation of productivity (Byrne, Fernald, Reinsdorf, 2016).

INDICATORS OF ICT USAGE BY BUSINESSES, HOUSEHOLDS (INDIVIDUALS), AND THE SOCIAL SPHERE (HEALTH AND EDUCATION)

The main areas of statistical surveying of ICT usage in the business sector are availability of ICT, objectives of the Internet usage, and results of such usage.

Statistical surveys of ICT usage by households and individuals measure availability of and access to ICT; use of mobile phones, computers, and the Internet (places of access, purposes and frequency of usage); ICT-related skills, etc.

Internationally applied indicators of ICT usage by individuals reflect differences between countries, and between various population groups in the same country, by the following parameters:

- Application of cutting-edge technologies to provide higher-quality Internet access;
- Use of opportunities provided by the Internet;
- Replacement of conventional forms of socialising, work, leisure, information

search, shopping, etc. with new Internet-based formats;

- Factors promoting or hindering ICT proliferation among the population.

Particular attention is paid to e-commerce and e-government indicators. Related aspects are analysed for enterprises and individuals.

E-commerce is the sale or purchase of goods or services conducted over computer networks by methods specifically designed for the purpose of receiving or placing of orders. The payment and the delivery of the goods or services do not have to be conducted online. E-commerce transactions exclude orders made by manually typed e-mail messages (Eurostat, 2015).

E-government is electronic contacts via the Internet with public authorities and some public services. Contacts through manually typed e-mails should be excluded. Contact and interaction with public authorities and public services include websites concerning citizen obligations (e.g. tax declaration, notification of moving), rights (e.g. social benefits), official documents (e.g. ID card, birth certificate), public educational services (e.g. public libraries, information on the enrolment in schools or universities), public health services (e.g. services of public hospitals) (Eurostat, 2015).

Surveying ICT usage in the social sphere, health, and education is also developing. Such surveys have a structure similar to those monitoring ICT usage in the business sector. They also cover certain specific issues, such as, in health—development of telemedicine, application of ICT to create and maintain medical registries and databases, provide electronic services to patients, etc.; in education, availability of various kinds of ICT in all types of educational institutions is measured, along with conditions for efficient application of ICT in teaching, ICT usage by teachers and students, introduction of new ICT-based teaching formats and techniques, etc.

All these standards use for estimating to indicators for monitoring and benchmarking on

sustainable development, international ranking, ICT development by region and country.

The Eurostat collected and analyzed data of the Information Society in the European Union (EU), focusing on the availability of ICT usage by individuals and within households (Eurostat, 2016b) and in enterprises (Eurostat, 2016c). The development of the Information Society is regarded as critical to meet the demands of society and the EU economy. The countries in other regions also show more active in implementing standards and shaping the data.

SOLUTIONS AND RECOMMENDATIONS

Despite this extensive methodological groundwork ICT development challenges of measurement.

First of all it relate of broadband Internet definitions. Broadband is defined as a service providing download speeds of at least 256 Kbit/s (ITU, 2011). In order to adequately reflect the development of high-speed Internet for broadband should consider starting with a speed of at least 2 Mbit/s.

Specifically, conducting surveys of ICT usage by households and individuals, international organisations typically consider all people living on the same premises, both related and unrelated to each other, as a household, if at least one of them belongs to the target population group. Recommended age range for the surveyed population is 16–74. Countries may collect data about individuals outside this age group (they might be particularly interested in ICT usage by people aged 75+). Many OECD member countries have actually extended this group and also survey people under 15. In about a half of the OECD member states the target group's age range was extended to 10–72. Some countries, such as Korea, Mexico, and the USA, even survey children aged 3–6. Many countries have also eliminated the upper age limit of the target group. Inclusion, the world over, of increasingly large population groups into the target group is due to the wide proliferation

of information technologies, and their penetration of people's everyday life at any age.

Some problems exist with collecting data for ICT infrastructure indicators. Currently, most of the ITU member countries provide data about revenues from all telecommunication services; from mobile communications; and data on investments in telecommunications. Meanwhile methodology for producing such data, and its availability remain a problem in a number of developing countries. In some cases, different methodologies may result in a significant distortion – up to 20–30%, which complicates comparing countries on equivalent basis and producing reliable global statistics.

FUTURE RESEARCH DIRECTIONS

Statistical approaches and indicators described above should be seen as basic ones. They are quite suitable for application in practically all countries. At the same time, ICT-involving processes are inherently so dynamic, and change so rapidly that statistical measuring techniques must be updated and improved all the time. There is a need to supplement conventional monitoring of Information Society with experimental indicators reflecting the Internet's impact on the economic growth (quantitative assessment of the Internet-induced openness's consequences in such areas as trade, innovation, entrepreneurship, and labour productivity); social wellbeing; countries' independence; their inclusion in the Internet environment; efficiency of digital resources' usage; managing digital security and privacy risk.

The Digital Economy now permeates countless aspects of the world's economy, impacting sectors as varied as banking, retail, energy, transportation, education, publishing, media or health. Information and Communication Technologies are transforming the ways social interactions and personal relationships are conducted, with land-line, mobile and broadcast networks converging, and devices and objects increasingly connected to forming the Internet of things.

To reflect the latest trends in the emerging Digital Economy, the Internet dissemination in all activities (horizontal penetration), digitalisation of each sector of the economy, and of every public service provision should be measured, together with development of broadband technologies, the Internet of things, personal data protection, children's network security and overall cyber-security, ICT impact on the environment, etc. (OECD, 2016).

The growth of ICTs has resulted in a rapid increase of new (including big) data sources, in particular from the ICT industry. The most international institutes with national experts are looking into innovative ways to utilize big data as a new data source, and to overcome important data gaps (UN, 2016). So it is very perspective way for development statistics.

CONCLUSION

Rapid development of ICT contributed to emergence of profound social and economic changes, new forms of socialising and interaction, and transformation of the whole society. An interest and a need to study this phenomenon arose, on national and international levels. At the same time demand for statistical data describing the new processes and trends has emerged, to support relevant political decision-making.

Official statistical data sufficient to monitor development of Information Society was always seen as an important tool for shaping international and national policies.

Three major sources of data describing ICT include the following: production statistics, telecommunications statistics, and ICT usage statistics. The first type of data, which characterises the ICT sector, Content and Media sector, and ICT products, is based on data of business statistics and foreign trade statistics. ICT infrastructure indicators are calculated on the basis of data provided by communication networks' operators. On the other hand, data on ICT usage are usually specially

collected and processed through targeted surveys designed to measure ICT usage by enterprises, households and individuals.

For compatibility and benchmarking purposes, it is important to adopt uniform methodological approaches to statistical measurement. This aspect is given particular attention when international standards are developed. Significant progress in measuring ICT was made in recent years, including monitoring of new technologies' and communication services' proliferation, horizontal penetration, and structural changes they engender. New study areas have emerged, allowing to measure the major transformations brought about by development of ICT.

Basic statistical standards actually applied by international organisations and various countries include the following:

- The ICT sector and Content and Media sector definition by economic activity in accordance with ISIC Rev. 4;
- The definitions and classifications relating to ICT goods and services based on CPC Ver. 2, HS2007;
- Apply other branch statistics (business statistics, foreign trade data, the system of national accounts, etc.) to calculate ICT supply and infrastructure indicators;
- A flexible data collection system; providing of standard questionnaire for specialised businesses and households (individuals) surveys;
- Adoption of agreed definitions (including for e-commerce, e-government, etc.);
- Development of internationally harmonised statistical indicators systems for measuring ICT, and principles of their calculation allowing to produce internationally compatible statistics, conduct international benchmarking, and analyse global information development trends.

However, given a rapid progress of ICT, its deeper and deeper penetration in all areas, and

comprehensive impact on economic and social development and the quality of life, there is an obvious need to further develop Information Society Statistics at both national and international levels to study new technologies and develop new data collection techniques, Big Data methods.

KEY TERMS AND DEFINITIONS

ICT Sphere: Supply, demand and usage of ICT.

ICT Usage Statistics: A sub-area of Information Society statistics studying all aspects of

activities involving application of ICT in the business sector, social sphere, public administration, households, and by individuals.

Information and Communication Technologies (ICT): Technologies using microelectronics for collection, storage, processing, retrieval, transmission, and presentation of data, texts, images, and sound (HSE, 2014).

Information Industry Statistics: A sub-area of Information Society statistics studying all aspects of the ICT and content-related activities.

Information Society Statistics: The newest branch of social and economic statistics aimed at studying all aspects of activities related to the production of ICT goods and services, distribution and usage of ICT in the economy, social and public sectors, and private life (HSE, 2014).

International Statistical Standards for Measuring ICT: A set of internationally accepted recommendations on statistical surveying of Information Society, specifying requirements to statistical data and describing methodology for building basic indicators, based on harmonisation of national statistical standards.

International Statistics: Harmonised statistical data collected and published by international organisations based on standardised programmes, to conduct regional and international comparisons.

Information Technologies and Social Change

Muhammet Ali Köroğlu

Uşak University, Turkey

Cemile Zehra Köroğlu

Uşak University, Turkey

INTRODUCTION

Change is an inevitable fate for all the communities of the earth. The thing making social change today more important is the speed of this change. In previous historical periods of humanity, changes lasting for centuries today occur in only a few years. On this scale, change requires a dissolution and restructuring from the interaction between generations to all social institutions. To adapt to such radical changes is not easy for any society. In fact, components of the social structure are protectionist and change slowly. Structures such as the culture, family, understanding of religion, economy, politics, and education do not change easily. But today, it is seen that all of these institutions change rapidly. Certainly social change depends on many factors such as cultural, environmental, demographic and so on. This is a natural result of the interaction between man and nature. It is the process of adapting human to life and nature. Thus, a slow and controlled change occurs. However, through the development of communication technologies in the 21st century, in terms of speed and direction, social change takes an unpredictable state.

The industrial revolution, affected mostly humanity and forced it to change via communication technologies. With the Industrial revolution, especially in Western Europe, the modern type of society emerged. Modern society organizes in hegemony of reason and scientific knowledge.

The idea of progress is dominant depending on the Enlightenment philosophy. Accordingly, societies progress continuously from primitive towards the modern. Modern society is the last stop. Industry creates an urban life depends on factory rather than a rural, earthbound life. Economics becomes an activity that occurs outside the households. Family and education change in structure and function. Politics ceases to be an event in king's palace. Relations between the governing and the governed, re-establish in the framework of citizenship.

Enlightened every citizen's political participation within the framework of wisdom and knowledge are accepted. Another important development emerged with the Industrial Revolution and modern society in mass media. Developing since the mid-19th century, high-circulation newspapers and magazines became the most important agents of change in modern society with the mass media such as the radio, cinema, and television. Especially since the 1920s, the role of the media and mass media have been discussed in influencing human attitudes and behavior. Thus, they have affected individuals and communities from the health to leisure, from the consumption to religion and family. They have accelerated social change in an unpredictable manner. Therefore, converter effects of communication technologies on the social structures and social relations will remain as the investigation area of social sciences for a longer time.

BACKGROUND

Classical sociology seeks social change in the relationship between social structures. Accordingly, an element of social structure affects the another structure by changing. Institutions such as religion, economy, family, and education create a social stability. As the first sociologists of modernity, Simon, Comte, Durkheim, Marx, Spencer and, Weber, in order to discover the laws of social change, try to produce information from social phenomena. Thus, an extensive literature occurs on the issue. In this context, theoretical approaches such as structuralism, conflict theories, evolutionism, functionalism and so on. can be mentioned (Comte, 2001; Weber, 2000; Durkheim, 2006).

In addition to these grand theories, with the development of communication technologies, theories about the culture created by these tools and its impact on human behavior and society remain. Studies on the impact of communication technologies on society and human relations gained momentum especially between the two world wars. Theoretical approaches such as Syringe Model, Limited Effects Approach, Usages and Gratifications Approach and so on. Approaches such as Criticism of Culture Industry of the Frankfurt School is important for literature. However, the approaches expressed in this literature deal with the impact of information and culture transmitted via information technologies on human. It is criticized that information and culture transmitted by the media and the mass media deactivate the society and the society is forced to consume a culture which is not produced by itself.

However, the internet and social networks opened to the public after 1985, giving the opportunity to participate. And their impact on society and human behavior is much deeper. They changed the traditional acceptance about crime, family, education, and leisure completely. Today, no social institution, is as effective on people and society as information technologies. Therefore, the interaction of communication technologies and society, should be re-evaluated based on existing

literature. Thus, it can be understood that how every social structure influenced and transformed by this process. This is the aim of this study.

THEORETICAL APPROACHES

When analyzing social sciences, the type of modern society presented after Enlightenment and Industrial Revolution have not sufficiently recognized the importance of communication technologies. Until the use of the Internet as public, as a means of mass media, newspapers, magazines, radio, and television have mediated a one-sided communication. Today, Internet and social media emerging attached to it, have come to the fore. Internet and social networks enclose social life in every aspect and the importance of it is increasing with each passing day. Thus, the platform created by the communication technologies become the center of life. There are significant effects of communication technologies on the images of human about life and world. Realities are created largely through the media in social and political life (Ergül, 2013, p.165).

Media concept includes both newspaper, and television as yesterday's communication means and internet and social networks. Studies deal with relations between means of mass communication and society have gone through several points. Until 1940, there was a strong belief that the media is a very powerful and has a convincing role is dominant. The dominant approach in this period is the Syringe model. Accordingly, media inject messages into the human brain like injecting drugs into the body (Gökalp, 2013, p. 27). Messages transferred by mass media to the recipients affect their behavior. Thus, to impress, to mobilize, to manipulate the masses and to change their attitudes, and to create perceptions are possible. According to this approach, one who control the mass media has the power to divert the masses as wished.

The first studies on the mass media were concentrated during the two world wars. To be under-

stood of importance of the propaganda during the war had an effect on this situation. Propaganda used by the parties in the war, had been effective on soldiers and civilians. This led to a separate propaganda war (Kağıtçıbaşı, 2012, p.192). This theory is a Social Psychological adaptation of Behavioral Approach in Psychology. Accordingly, the individual receives the transmitted message, learns the message, and reveals attitudes and behaviors accordingly. Hence, especially in the marketing field, there has been a number of studies on the power of advertising on consumer behavior.

Another important era in the field of communication technologies is the period between the 1940s and the 1960s. During this period, the political atmosphere in the world softened and the totalitarian threat passed. With the rise of the welfare state and economic relaxation, the service sector became widespread. Official monopoly began to disperse in communication technologies. Under these circumstances, instead of “Approach of Unlimited Power of Communications Technology”, “Understanding of the Limited Effects” developed. According to the “Limited Effects Model”, communication technologies reinforces the already existing attitudes and behavior in the receiver. The audience developed mechanisms such as selective attention, selective perception and selective recall against the message transmitted via communication technologies. So the audience protected himself against a message conflicting with his idea, attitudes, and behaviors (Türkoğlu, 2010, pp.113,114).

Another approach that emphasizes the limitations of the impact of communication technologies is the “Uses and Gratifications Approach”. In this model developed from a functionalist perspective, communication technologies and given messages are less important. In contrast, it is important that people use communication technologies to meet their needs. The audience is not in a passive consumers position. On the contrary, according to their needs, act selectively (Mutlu, 1994, p.140). According to this, different people can use the technology for different purposes in different ways.

This and similar approaches about communication technologies have been developed in conjunction with social theories such as Functionalism and Pluralism. Both approaches are not critical to society and politics. Functionalism has installed the role of the transfer of values to preserve a stable society to communication technologies. However, Pluralism has assumed that different groups in society can make their voice heard through communication technologies (Gökalp, 2013, p.31). Although Functionalism is a classical Sociological theory, Pluralism is specific to modern society. According to this approach, through communication technologies, each social formation from political parties to pressure groups or minority groups can express themselves. Communication technologies can not be the monopoly of a single group, therefore, groups competing with each other can express themselves.

Thus, communication technologies, along with other structures of society can produce and protect values which create collective consciousness and make it alive. Therefore, in general, media and privatization of the media, even to be dependent of media to some economic powers through advertisements have not been considered as problems. In terms of analysis of culture created by communication technologies, The Frankfurt School has a very important place. The Frankfurt School represents a critical tradition. This criticism is not limited by media or communication technologies. In fact, the Frankfurt School makes a comprehensive criticism of reason, science, and social world based on Enlightenment. In this context, means of mass communication are considered as instruments of culture industry. Culture, art and information transmitted by the communication technologies are produced for mass and consumption. Receivers consume this culture passively. Before everything this is an economic sector. It works according to the principles of profitability. This relationship elicits a quality problem.

According to this approach, the industrial production of cultural heritage commodify culture. Modern civilization ascribes to everything the

similarity. Culture industry to meet the numerous requests produces standard goods (Bal, 2013, p.108). The goal here is to force individuals into appropriate consumption patterns which belong to their status groups and to justify the existing economic structure. Additionally, technical, economical, and organizational requirements also determine the production of culture (Atiker, 1998, p.52). Furthermore, mass culture has created artificial and incorrect needs in individuals through the culture industry. As a result, it turned into an anonymizer ideology passivating masses (Stauth & Turner, 2000, p.407). All mass culture under monopoly is an identical culture and at the same time, It is a bad culture as a result of the combination of culture and entertainment.

Between advertising and culture industry has formed an identity in terms of being orientation methods. With the victory of the advertisement on cultural industries, consumers have begun to feel compelled to use the products of this industry (Bottomore, 2013, p.63). Thus, the culture industry, instead of directing consumers to think, has accustomed them to accept the ready. As a result of this, individuals have become passive tools of mass culture. Different communities living in different regions of the world have already begun to consume the products of the culture industry. This has meant the erosion of cultural diversity and one-dimensional human.

Culture industry criticism of the Frankfurt School is still worth discussing in many ways. However, there has been new advances in communication technologies after the 1970s. The keyword of this advancement known as Information Revolution has been “combination”. With advances in the information storage and its operating, large quantities of information could be shared instantly with systems such as advanced satellite and cable (Kejanlioğlu, 2004, p. 81). Thus, computers, in a very short period of time, have become indispensable by wrapping human life. To meet the needs of people, many versions of the programs and softwares have been produced. Development is still ongoing and there is no limit.

Through computer technologies, the Internet and social networks have become involved in human life, so everyday life has almost been moved into the virtual world. Internet is an alternative environment to the real-life world where many relationships and efforts from shopping to information access, education to artistic efforts, interactive relationships to images and information stocks have been experienced (Esmer, 2011, p. 249). Internet and social networks are different from the communication means such as newspaper and television. Such mass media is one-way and has a centralized structure. The internet is not centralized. Communication is bilateral. The user is not only receiver and consumer but also producer and distributor. Internet, due to its interactive nature, is a constantly transforming and reshaping communication environment (Gökalp, 2013, p. 47).

Therefore, the reality produced in such a communication world is temporary, rootedless and recurring. In fact, according to Baudrillard (Baudrillard, 2014, pp. 110,112,160), it consists of simulation because now the reality is not produced as rational, depending on an origin; it is reproduced through an operational model. In today's world where the principles of simulation is decisive, the reality only proves the existence of the model. Additionally, more information and news are produced every day, but less meanings are produced. Communication technologies destroying the contents produced by themselves are also destroying the social area. Now, virtual and reality are mixed and virtual has become the preferred to the reality. In short, simulations are more real. Thus, the world of everyday life is lost and society is getting individualized.

SOCIAL INSTITUTIONS AND TECHNOLOGY

How does such a communication world affect the basic structures of the society? Today, in this context, it is necessary to concentrate and do more

studies. Indeed, institutions such as religion, family, economy, education, politics and leisure are subjected to a conversion. Direction and end of this conversion is non-specific.

When evaluated specifically, family is a universal institution enabling the continuation of generation and socializing people. Family unity, for both sides, refers to a meaning and value above all. Partners come together to combat all kinds of challenges that life confronts with them. In today's world of communication, family has been reduced to contractual, spatial, and sexual partnerships. The rate of divorce is almost more than the rate of marriage. Of course, in this case, the share of culture industry is huge. All over the world, in works produced by the culture industry, eternal love, eternal happiness, unlimited romanticism are offered as the values of marriage. With marriage, couples understand that eternal love is a literary fantasy and then they begin to complain about lack of understanding. Also many researches show that intensive use of communication technologies has negative effects on the level of satisfaction in marriage. Indeed, the purpose of use of new communication technologies such as social media by couples represents different meanings in terms of gender norms. (Dew & Tulane, 2015, p. 626; Sekam, 2011, p. 274). Therefore, the purpose of use of communication technologies is an issue that should be questioned.

Today, divorce is one of the most serious family problems. There has been a significant increase in divorce rates throughout the world. Divorce leads to serious personal and social problems for individuals (TUIK, 2006). Feeling of failure, loneliness, concerns of being unloved, and stigma are some of these consequences. If they have children, this leads to other problems and challenges (Zastrow, 2013, p. 261). Therefore, the social functions of the family are fading. In contrast, cohabitation, virtual wedding, virtual infidelity, virtual love will be more valid. Still, current functions of family such as continuation of generation, socialization of the new individuals, providing emotional satisfaction will be more

minimized. In fact, with today's technology it is possible to live love someone in Asia with who living in America. The same person can find a surrogate mother who lives in Europe, send the sperm to have a child and grow his child through social services. Considering that children socialize via internet more than family, this will be even more rational choice.

Another social institution affected by the communication technologies is politics. Politics is a universal and fundamental institution providing the public order and performing general administrative. As such, it is a parallel phenomenon to the existence of humanity (Aydin, 1997, p. 143). In the very long history of humanity, politics was an event closed to the participation and limited by the palace surroundings. However, with the development of written communication technologies, political issues have become topics that more people are interested and have information about it.

Governance has been forced to be more transparent than in the past. Especially after the development of radio and television broadcasting, governance has been able to hide less things. With the development of Internet and social networks, state secrets have decreased more. However, this does not mean that everything is transparent. Regarding the issue, Habermas considers that communication technologies are tools for both formation and transformation of public sphere which is a political participation area. Initially, newspapers and publishing houses are tools providing public expression of ideas. However, later, news has become itself an economic value and these tools are isolated from the public contents (Habermas, 2002, p. 318, 319). However, today, there are numerous comments that Internet contributes to the spread of the pluralism.

Accordingly, the Internet increases social participation. In this regard, communication technologies are great equalizers (Bozkurt & Baştürk, 2013, pp. 411, 412). In contrast, those who disagree with techno-policy express that the arguments in favor of electronic democracy do not understand the nature of politics. Democracy

includes political negotiations, judgment, and face to face discussions. This negotiation occurs under the guidance of rational reasoning and principles of political discourse and takes shape in a mutual discussion aiming to reach a consensus. However, all communications and discussions arising from the media are the death of policies based on rational negotiations. Additionally the internet is a distorted form of political debate drawn into the manipulative, extreme, and sensational (Kellner, 2004, p. 716).

Theoretically, people from every class, status, ethnic, or minority groups can share and defend all kinds of ideas on the Internet independently from the state repression and legal limits. This is a pluralism. However, this does not always create a rational negotiation or a social consensus. Nevertheless, the virtual environment can mediate to the opposition and restrict government's actions. In this sense, the control of the virtual environment is virtually impossible. For example, during the process of the Arab Spring, the opposition was organized via social media and able to conduct mass actions. In this respect, social networks allow the creation of virtual congregations and communities exceeding color, status and national boundaries. Therefore, there will be many social movements on a global scale in the future.

Similarly, economic relations will continue to be made over the Internet and face-to-face relations will be further reduced. The culture created by ICTs will continue to determine people's need for goods and services and their consumption preferences. Capitalism and its values will be more widespread on a global scale. How this process will affect the global economic inequality is unclear. Likewise, educational institutions will be forced to move away from their traditional format. Options such as education at home and distance learning will occur more smoothly. The institution affected by the development in communication technologies as a minimum will be religion.

Although religious insights and congregation patterns are influenced by this process, religion is still the source of truth and meaning for many

individuals and society. Communication technologies can increase pluralism in religious thought, contribute to the development of religious thought and create new religious congregation patterns. Discussions about the truth value of religion as a total system, still will continue to be carried out within the framework of the relationship between religion and science.

FUTURE RESEARCH DIRECTIONS

When evaluated generally, during the development of communication technologies, many studies have been conducted in terms of impact of message on the recipients. During the two world wars, controlling communication technologies was understood as almost to control the whole society. In determining human behavior, has been focused on the impact of communication technologies. But after the 1940s, especially with the development of Social Psychology, there has been more concentration on the multidimensionality of human behavior. The idea that the mass which is collocutor of the communication technologies is not completely passive has gained importance. Together with the emergence of the internet and widespread use of it, a new period has begun. The most important feature of this period is becoming communication interactive.

Studies on communication technologies are carried out in the framework of themes like advertising, marketing, management, attitude and behavior change and so on. However, more studies are needed to be done about the impacts of communication technologies on the basic institutions and structures of societies. In particular, a new era has begun with internet; technology and network has affected more all societies structurally. Therefore, there is a need for more research regarding impacts of communication technologies specifically on the family, religion, education, culture, politics and public policies. Similarly, transformation of everyday life should be evaluated in this context. Dimensions of communication technologies which

contribute to human freedom and creativity should be taken forward.

CONCLUSION

Communication technologies have shown a very rapid development since the mid-19th century. Specifically, through radio and television broadcasting, they have entered into people's lives more and gained an important place. Thus, the space and distances have lost meaning. About the impact of mass media on human life and society, the Frankfurt School has represented critical tradition. Social processes taking place on the concepts of mass society, consumption and culture industry has been criticized. This criticism has been in line with modern society's acceptance and values. Many of these criticisms still remain actual.

Real revolution in communication technologies has been realized through the publicity of internet that enables interactive interaction. Today, people spend a portion of their lives in front of TV screens, as they spend a large portion of them on Internet. Social relations are affected more than the new process. On one hand, individuals are lonely, but on the other hand they socialize on the internet. In this way, sense of loneliness is further increased. Society is more individuated, life world and the field of everyday affairs are narrowing. The most basic and universal institutions of humanity transform functionally. The future will be somewhere in the intersection of virtual and reality. Pessimism and hope for humanity have the same value. It is very difficult to predict the future or changes will be experienced. However, it is sure that all aspects of individual and social life will be affected and transformed.

KEY TERMS AND DEFINITIONS

Cultural Structure: Spiritual aspect of social structure emphasizing human relationships.

Culture Industry: Industrialization of culture and commodification of cultural products.

Information Technologies: The tools that are generating, accumulating, and, protecting information.

Mass Culture: A form of culture produced by the culture industry.

Modernity: The name of values system emerged in the 17th century in Europe.

Social Change: The change of social structure, culture and, social behaviors in a society.

Social Structure: A set of organized relationships in a society.

*i*Schools Promoting “Information Science and Technology” (IST) Domain Towards Community, Business, and Society With Contemporary Worldwide Trend and Emerging Potentialities in India

P. K. Paul

Raiganj University, India

D. Chatterjee

Seacom Skills University, India

INTRODUCTION

There are so many opportunities that come with iSchooling in terms of courses, research, job potentialities and interdisciplinary skills. Though it deals with some problems and challenges; this paper is talks about such preliminary aspects, emerging trends and possibilities in Indian context with international agenda. The chapter is illustrated some possible programme and nomenclature in this context of People-Information-Technology interaction. This is treated as a healthy and sophisticated academic innovation in the field of information, knowledge, computing and technologies where some schools have been merged into a big academic unit or school. USA is a pioneer in this regard where several information schools such as Information studies, Computer science, Management Science, Knowledge Management have been merged. And in emerging context, altogether such combined subjects called as ‘Information Science & Technology’.

BACKGROUND AND ORIGIN OF I-SCHOOLS

I-Schools gained popularity during 1990’s when internet reached the common people and other commercial ventures. It is in this time the explo-

sion of information has lead the development of healthy information management approach. Earlier evolution of I-Schools provided such knowledge as Library Science, Communication Science, Mass-Communication, Computer Science and Information Technology. But the interdisciplinary research lead to a closer interaction among these departments and subjects and ultimately a new academic unit called I-Schools or Information Science/ Information Science & Technology (IST) Schools or Information Schools evolved. I-Schools gained popularity during 1900 -2000 (*Abeysekera, I. and Guthrie, J. (2004), and Agarwarl, Suren, 1989*). In this period many new I-Schools emerged not only in USA but also in Europe, and African countries, though the trend was much less in Australia and Asian countries including India. I-Schools in some universities evolved as new academic and research units. However in some of the universities it was established by merging the related disciplines with computing and/or information. I-Schools today has gained a separate recognition in the academic world due to its significant role and incredible benefits.

METHODOLOGY

It is a fact that, still research on nature & domain of Information Science is tough to find out in

DOI: 10.4018/978-1-5225-2255-3.ch410

academic community; hence it is urgent to find out the role of Information Science or Information Science & Technology (IST) in several community; and complete Social development by the review of literature and other mode of Scientific Research. Practically, it is still tough to dig out the latest area and field of Information Science and this research work will be helpful to find out such domain. To conduct this study various tools and techniques have been used, out of which review of literature played an important role. Web Review plays an important role to find out running courses in the field of Information Science & Technology (IST) and other information and related departments. To assess educational situation and make SWOT analysis of this field, some websites were searched; these are official websites of UGC; AICTE; Government of India. The MSc- Information Science curriculum, Courses and programme structure of more than 600+ educational institutes have been assessed during this study and the main link of UGC, AICTE and MHRD have been used to find out the latest of Education Information in India.

FEATURES OF I-SCHOOLS

The establishment on *iSchool* originated during 1988, when eminent educationist and Information Scientist, Toni Carbo, School of Information Science, University of Pittsburgh; Donald Marchan, School of Information Studies, Syracuse University and Richard Lytle, College of Information Science/Information Science & Technology (IST) and Technology, Drexel University joint hands for establishment of Information association called *iSchool* Caucus. After few years in 2001, the three members' team expands to 'Gang of Five' and then in 2003 some more dean of several Information related schools join the forum and as so August, 2015 total 65 institutes fall under the same. I-Schools or Information Schools are the academic units which are dedicated to the information solution through academic and research outputs. It is primarily responsible for the collection, selection, organization, processing, management

and dissemination of information with the help of Technologies. The main difference between IT Schools and I-Schools is that, IT Schools provide Technological Manpower and solution such as database, Networking, Software, Hardware and Core Computing, Multimedia and image processing, whereas I-Schools are responsible for the Information solution or knowledge Management solution with the help of Technologies such as Database Management, Networking Technology, Multimedia Technology, Communication Technology and Web Technology. Thus I-Schools are dedicated to information solution powered by technologies (*Balwan Singh, 2004 & Paul, b, Kumar, 2012,*). I-Schools are also responsible for Information and technological application in society, commerce, health and governance. Thus I-Schools deal much more with societies and believe in interaction between Information, Technology and Society Where as IT Schools deal just about application rather than societal approach. LIS schools deal with information solution in library and similar foundations, I-Schools deal and works with several domains and institutions (*Vickery, B.C., & Vickery, A. 1987 & Paul, c 2012*).

I-SCHOOLS AND I-PROGRAMS: EXISTING AND POSSIBILITIES

I-Schools offer so many programs but majority of them are in Applied Science. The flagship program in most of the academic units is Information Science and the degree as MS/MSc (Information Science/Information Science & Technology). However apart from these, I-Schools offer some specialized information programs also such as—

- **MSc/MS/BSc/BS:** Information Science/Information Science & Technology (IST) (Human Computer Interaction)
- **MSc/MS/BSc/BS:** Usability Engineering
- **MSc/MS/BSc/BS:** Digital Repository
- **MSc/MS/BSc/BS:** Communication Systems
- **MSc/MS/BSc/BS:** Database System

Figure 1. From Smaller and Broader periphery of Information and Technology related field

However some Universities also offer domain-based Information Programs such as Telecommunication Technology, Communication Systems, Multimedia Systems, with full fledged BS/MS degree (White, H. D., & McCain, K. W., 1997). Information Schools also offer domain based Information Programs as full fledged academic degree with specialization in Information related programs (Though Information Schools not at all offer conventional IT program such as Computer Science, IT, Computing, Software Engineering and so on.) (Buckland, Michael K and Liu 1995 and Bansal, 2005, C. Wang, 2010). The programs are as follows:-

- **BSc/BS/MSc/MS:** Information Science/Information Science & Technology (IST)
- **MSc/MS/BSc/BS:** Geoinformatics
- **MSc/MS/BSc/BS:** Medical Informatics
- **MSc/MS/BSc/BS:** Bio- Informatics
- **MSc/MS/BSc/BS:** Music-Informatics
- **MSc/MS/BSc/BS:** Library Management
- **MSc/MS/BSc/BS:** Chemo Informatics
- **MSc/MS/BSc/BS:** Quantum Informatics

- **MSc/MS/BSc/BS:** Social Computing
- **MSc/MS/BSc/BS:** Social Informatics
- **MSc/MS/BSc/BS:** Archive Studies and so on

Thus Information Science/Information Science & Technology (IST) may possibly be offered in IT degree programs such as –

BCA/MCA (with domain based specialization such as Geo-Informatics/Medical Informatics / Bio-Informatics/Library Management/Bio Informatics/Quantum Information Science/Social Informatics/Social Computing).

Information Science/Information Science & Technology (IST) can also be offered as Fundamental program in BCA/MCA (Information Science/Information Science & Technology), which will be better for healthy computer Information Infrastructure Management (Wersig, G., & Neveling, U. 1975). It is possible to start new programs in I-Schools such as Engineering, BTech/MTech (IS) or BTech/MTech in the ECE/IT or related fields with IS specialization or it's any domain based specialization.

Figure 2. Advances of Information Programs with Interdisciplinary approaches

I-SCHOOLS IN INDIA: CURRENT SCENARIO AND FUTURE POTENTIALS

It is a fact that in India any strategy has not been at all adopted by the universities and higher Educational Institutes. India is one of the largest education hub in the world with more than 600 universities, including Central, State, Private and Deemed universities. Apart from universities, Institutes of National importance such as NIIT's, IIT's, IIM's, over 38000 Colleges serving for Indian students. Today nearly 5000 Engineering colleges and Polytechnics also provide oxygen to technical manpower and technological solution (Paul, f 2012). In India, most available information related subjects are Information Science (very few), Library Science (very common), Communication Studies (mainly in universities), journalism and mass communication. However, some universities also offers corporate communication, Information Systems, Electronic Information Systems which also fall under the I-School periphery.

The most common program of Information Science/Information Science & Technology (IST) in India is Library and Information Science which actually deals with library, Information Centers and similar foundations, i.e., the course is based on Information Science and Library Science interaction. Around 300 universities offer LIS program under the nomenclature BLIS, MLIS and in some cases BLIB/MLIB with MPhil and PhD level. The LIS programs are available in Regular and Distance modes and also online and off campus modes in many universities. This program is suitable for library management and deals with so many library aspects including some Information and Technological Foundations. The manpower such as Librarian, Cataloguer, Classification-ers, Indexer, Abstractor, Reference In-charge, Documentation Officer, Information Officer are provided by Library and Information Science.

The other Information related programs like Communication studies are available in very few universities and provide jobs such as, Communication Officer, Corporate Manager, and Information Manager. The Journalism and Mass Communica-

tion course provide manpower to the field of news paper and communication industries (Cohen, E. B., & Malgorzata, N.2006; Martin, 1998).

Thus, in India most of the Information programs are concerned with Library or communication industry. The general biased-free information program 'Information Science/Information Science & Technology (IST)' is available only in some of the institutes. Among them, BIT, Mesra is the first one who introduced MSc Information Science. The same program is offered by MCIS, Manipal University, Karnataka, IEM-Salt Lake, KITM-Buniadpur, DATM-Alipurduar, Techno India-Salt Lake, Techno India-Hooghly, DSMS- Durgapur. Periyar University is another which offers MSc (Information Science) and BSc(Information Science). This is the only university which offers BSc (IS). However depending upon application and special condition some universities permit admission in MPhil/PhD- Information Science. Most Universities offer individual courses and course gradients. Information Science (IST) in MCIS and Periyar University are biased with IT and Computing rather than main facet of I-Schools Information or knowledge. However BIT, Mesra offers MSc- Information Science which is based on both computing and Information Fundamentals (Such as indexing, abstracting, cataloguing and classification), Thus students becomes eligible in both library related jobs opportunities as well as in the Computing positions which are based on information. Information Scientist, CTO, CIO, IN, Network Administrator, System Administrator, Web Administrator, and Usability Engineer are the main job positions which may be availed of by the Information Science students. But the supply of students is very insignificant in India.

Information Schools with I-School flagship/ nomenclature are run by International School of Information Management (ISIM), Mysore University which offers a special information focused M.Tech. Programme i.e. M.Tech.-Information System and Management first time in Asia.

Specialized domain based Information Programs such as health Informatics, Medical Infor-

matics, Quantum Information Science, Chemical Informatics, Geo-Informatics are offered in very few educational institutes. However such programs are not offered in I-Schools or Information Science/Information Science & Technology (IST) Programs/ Departments. The programs are mainly offered in the related fields such as Geo Informatics, in Geo Science/ CSE/IT departments, Bio Informatics, Health Informatics, in Medical Programme. Medical Informatics, Chemo-Informatics, Quantum Informatics, Music Informatics are not offered in any of the universities.

WAY TO BUILD I-SCHOOLS IN INDIA

Information Science/Information Science & Technology (IST)/IST is very much diverse in nature and focused with so many domains and challenges its style depending upon need, place, country, school & international nature. Though, this research based chapter work is included to find out latest on IST/IS worldwide listed school (listed by Asia Pacific iSchools consortium); which is also indirectly helps to design programme on IST/IS in Indian concentration. But focuses is on designing with MSc/BSc programme. Though still potentiality is exists on nomenclature with BE/ME/BTech/MTech and so on.

Information Science/Information Science & Technology (IST) (and similar) as a domain become more popular and emerging with both Computational and traditional point of view. Depending upon demand and country the nature of Information Science/Information Science & Technology (IST)/IST are different with several nomenclatures. In this chapter review is carried out in the context of Information Science/Information Science & Technology (IST) as a programme; which is mainly concentrated on Asia and India. For critical analysis of Information Programs and domain so many nomenclatures are handle. As Information Science/Information Science & Technology (IST) is a big domain (combine with Computer Science, Computer Application,

Computer Engineering, Information Systems, Information Technology, Information Studies, Management Information Systems, and other domain); thus, in this chapter computing related programs are also included in Indian context. Chapter mentions about some IST Courses or Programs which are available with 'Information Science nomenclature throughout India Information Schools in India can be built institutionally or supported by the Government or Universities for the tremendous importance of information and knowledge.

Though Information Schools can be built by merging related departments of the universities, such as IT, CSE, CA, LIS, Mass Communication, departments of management and social studies may also be involved in I-Schools for better professional and research results. A full-fledged I-School/department may be established with some fulltime faculty and some adjunct professors from the IT, CSE, CA, Management departments depending upon the need. However, another approach may be starting of full-fledged Information Schools as University. In some countries universities with full-fledged Information Science programs have already been initiated. The Wuhan University of China has established a school focusing on IST. Instead of schools/department, in many countries special full-fledged universities have been established. For example, Tokyo University of Information Science & Technology (IST) & Technology, Japan; Beijing University of Information Science & Technology (IST) & Technology, China; University of Information Science & Technology (IST) & Technology, Ohrid-Macedonia. These Universities are the prime examples of IST development, application and movement. It is possible to establish a university with IT department, CSE, Management, Information Systems department with a strong focus on Information and Knowledge and Human Interaction with Technology and common people. Here the department will not only deal with conventional structure but also will be able to work like a big department. Thus it will promote interdisciplinary researches.

Engineering Colleges in India who are big players can start I-Schools or its related programs such as ME, ECE, IT, CSE which shall integrate each other. They can offer Information Science/Information Science & Technology (IST) as B.Tech./M.Tech.-ECE- Information Science & Technology (IST), B.Tech./M.Tech.-IT- Information Science & Technology (IST), B.Tech./M.Tech.-CSE- Information Science & Technology (IST).

I-SCHOOLS AND ENGINEERING INFRASTRUCTURE IN INDIA

India has sufficiently many Engineering institutes and academic units in Indian universities and degree colleges. It has nearly 5000+ technical institutes which include engineering colleges (*run under the affiliation of a university and approval of AICTE*), Polytechnics, Management and Administrative Colleges. Engineering Degree programs and general Degree courses are offered including 'BE or Bachelor of Engineering' / 'B.Tech. or Bachelor of Technology'.

This degree is offered mainly in core Engineering subjects or Soft Engineering subjects. The most common subjects are

- Electronics and Communication Engineering (ECE).
- Electrical and Electronics Engineering (EEE).
- Electrical Engineering (EE).
- Civil Engineering (CE).
- Mechanical Engineering (ME).
- Aeronautical Engineering (AE) and so on.

However, apart from core subjects mentioned above some modern and interdisciplinary subjects are also offered in Indian Universities/ Engineering Colleges in their BE/BTech programs. These programme subjects are:

- Bio Technology.
- Structural Engineering.

Figure 3. The nature of Information Studies emphasizing origin of Information Science/Information Science & Technology (IST) (IS)

- Water and Resource Engineering.
- Environmental Engineering.
- Printing Technology.
- Geo Engineering and so on.

However, the mentioned subjects are offered in the Master of Engineering (ME)/ Master of Technology (MTech) programs with some specialization apart from the main subjects such as MTech-Electronic and Communication Engineering (*VLIS Design*). Here VLIS Design may be treated as specialization in Electronics and Communication Engineering (ECE). Thus this way some popular and flagship programs of Information Schools/ I-Schools may be introduced with Engineering Degree (*Like-BTech/MTech*). The possible degree programs may be:

- BTech/MTech- Mechanical Engineering (Information Science/Information Science & Technology (IST)).
- BTech/MTech- Electronics and Communication Engineering (Information Science/Information Science & Technology (IST)).

- BTech/MTech- Electrical and Electronics Engineering (Information Science/Information Science & Technology (IST)).
- BTech/MTech- Computer Science and Engineering (Information Science/Information Science & Technology (IST)).
- BTech/MTech- Information Technology (Information Science/Information Science & Technology (IST)).
- BTech/MTech- Software Engineering (Information Science/Information Science & Technology (IST)).
- BTech/MTech- Communication Engineering (Information Science/Information Science & Technology (IST)).

Some other engineering domains which are related to Information Schools such as Information Science/Information Science & Technology (IST)/ Information Systems/Information and Knowledge Management/Digital Media Communication can also play a pivotal role in this regard. Thus, it is possible to offer Information Programs only with the Engineering disciplines having Computer or Electronics or Information domains.

It is a fact that BTech/MTech Degree is still not offered with Information Science/Information Science & Technology (IST) as the main subject; but there is a huge possibility with 'Information Science/Information Science & Technology (IST)' or related information programs with Engineering Degree. If it is not a full-fledged department, then it can be offered with some other department such as Electronics and Communication Engineering/ Computer Science and Engineering/ Information Technology/ Software Engineering/ Mechanical Engineering and so on. Adjunct Professors may be a good alternative in this situation.

Virtually, MTech-Information Science/Information Science & Technology (IST) is also possible with so many specializations (*like BTech/MTech- Computer Science and Engineering offered with VLIS Design, Information Security, Embedded Systems and so on*).

However, the concerned specializations need to be offered only with information and knowledge domain. Some possible degrees with Information Science/Information Science & Technology (IST) specializations may be as follows:

- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Cloud Computing).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Usability Engineering).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Human Computer Interaction).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Information Architecture).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Interaction Design).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Green Informatics).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Geo-Informatics).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Database Management).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Multimedia Information Systems).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Web Technology).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Big Data Management).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Knowledge Engineering).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Networking Technology).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Library Management).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Decision Support Systems).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (ERP).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Library Automation); and so on.

Apart from specialization in skill based practice subjects, BTech/MTech-Information Science/Information Science & Technology (IST) may be offered in some theoretical subjects as well such as

- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Digital Dived).

Figure 4. The main components of Information Science/Information Science & Technology (IST) (IS) and its ultimate results

- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Information Literacy).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Information Systems).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Information Resource Management).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Knowledge Organization); and so on.
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Health Informatics).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Bio Informatics).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Geo Informatics).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Chemo Informatics).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Quantum Informatics).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Medical Informatics).

As Information programs have connection with other domains, Information Science/Information Science & Technology (IST) in Engineering may also be offered in subjects such as:-

- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Nuero Informatics).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Business and Retail Information Systems).
- BTech/MTech/BE/ME- Information Science/Information Science & Technology (IST) (Social Computing/Informatics).

Thus Information Science/Information Science & Technology (IST) and other Information Programs (*Like- Information Systems/Information and Knowledge Management/Digital Media Communication*) may be introduced in Engineering colleges and universities with main Degree (like *MTech-Information Science/Information Science & Technology* or specialization of Information Science/Information Science & Technology (IST) in other Engineering Degrees like BTech/MTech- Electrical and Electronics Engineering (Information Science & Technology); or MTech-Information Science & Technology (IST) with specialization in core and allied Information Areas with skill based nomenclature (BTech/MTech/BE/ME- Information Science & Technology (IST) (Usability Engineering) /(Cloud Computing) or domain based nomenclature like BTech/MTech- (Health Informatics)/ (Quantum Informatics) and so on. Joint Venture, Collaboration, Adjunct Professorship may be good solutions at the initial stage to introduce these Information Programs in India; especially in Engineering domain. Thus I-Schools may get new oxygen this way.

CHALLENGES

This Research & Development is specially designed to find out latest on 'Information Science or Information Science & Technology including contemporary programme, nature, duration, specialization worldwide. But it is very much tough to find out latest scenario of Information Sciences

in universities worldwide (located more than 200 countries).

Hence here I-School organizations mainly chosen (which combines IST offering schools/programs worldwide); as they are not only consortium of Directory of 'IST/IS' offering schools but also included only such institutes who's agenda is interaction of 'Information-Technology-People'. Thus, this research work is based on this agenda; and only analyzes and, interpreted and includes programme/nature of Information Science/Information Science & Technology (IST) concentrated on interaction on 'Information-Technology-People'.

As far as Indian educational aspects are concerned, it is one of the largest country in the world with more than 35000 higher educational institutions/ colleges, 500+ Engineering/Technical Institutes, 700+ Universities and nearly two hundreds of centrally funded Institutes including IITs, NITs, IEST, IESR, a large number of institution under CSIR (12). Yet efforts to build I-Schools or information related academic unit/s programs are very less. Governmental supports, planning from educationalists, University level efforts is minimum. However many students of IT/ CSE are absorbed by the MNCs and other employers and then they make them ready for their job. But a simple way is to get ready-professionals is by introducing I-Schools or its related academic programs. Want of Planning, funding, efforts and less academic and professional associations in this field is the main reason for undeveloped or under developed situation of I-Schools in India.

FUTURE RESEARCH DIRECTIONS

Information Science/Information Science & Technology (IST) is very much diverse in nature and focused with so many domains and challenges its style depending upon need, place, country, school & international nature. Though, this research work is included to find out latest on IST/IS worldwide listed school. Information Science/Information Science & Technology (IST) is an important are

of Applied Science and Technology. This paper illustrates so many aspects of this domain and current situation and future possibilities in Indian and worldwide scenario. Here for future I-Schools, so many courses are proposed with related department and possible offering. Thus in future it is possible to design and develop each programme depending upon educational norms and requirements of various countries. 'Time Limit' is another limitation of the research work. The scope of the research is very broad; hence works may be carried out in so many sub divided areas depending upon further review, need and so on.

CONCLUSION

'Technologies are main pillar in this age' and if it is Information Technology then there is no doubt regarding the slogan. Internet was the last emerged tool of Computing and recently some more tools and name are shining such as Cloud Computing & Virtualization, Big Data Management, Intelligent Analytics, Green Computing & Technology (N. Chandrakant, 2011 & 2013). And all such fields are need to incorporate in the Information Science/Information Science & Technology (IST) and or allied domain. Information Science in general may help concerned field in many ways. It is able to develop a relationship between information-technology and people or stakeholders of the concerned field. With thousands of educational institutes it is possible to build independent I-Schools separately but if it is impossible initially it may be built by joint ventures with other departments. Employers, associations need to develop awareness to give pressure for starting I-Schools to prepare professionals from the I-Schools who are not only able in information but also in technologies and their applications in the society / community or respective fields.

KEY TERMS AND DEFINITIONS

AICTE: All India Council for Technical Education responsible for the Engineering, Technical and Management Education in India.

Computing: Includes designing and building hardware and software systems for a wide range of purposes; processing, structuring, and managing various kinds of information; doing scientific studies using computers; making computer systems behave intelligently; creating and using communications and entertainment media; finding and gathering information relevant to any particular purpose, and so on.

Information: Information as a concept has a diversity of meanings, from everyday usage to technical settings. Generally speaking, the concept of information is closely related to notions of constraint, communication, control, data, form, instruction, knowledge, meaning, mental stimulus, pattern, perception, and representation.

Information School: Academic units which work for professional and academic solution of Information and Technologies. Information Schools are responsible for providing manpower

in the field of Information and Technologies and Computing. I-Schools gained popularity during 1990's when internet reached the common people and other commercial ventures. It is in this time the explosion of information has led the development of healthy information management approach. Earlier evolution of I-Schools provided such knowledge as Library Science, Communication Science, Mass-Communication, Computer Science and Information Technology.

Information Science: A discipline of disciplines that came from the subject which deals with information, information services, information activities and digital information. So mainly from

library science, archive science, documentation science, computer science it has originated; however this is not truly computer science nor library science. This is an interdisciplinary science; which is a combination of Library Science, Computer Science, Information Technology, Management Science, Operation Research and the subjects that deal with information.

Interdisciplinary: Connection between some subjects irrespective of domain and direct and indirect connection with main facet or sub field.

UGC: University Grants Commission is the main regulator of Universities of India, Including Central, State, Private and Deemed.

Logic Programming for Intelligent Systems

James D. Jones

Liberty University, USA

INTRODUCTION

In what seem to be never-ending quests for automation, integration, seamlessness, new genres of applications, and “smart systems”, all of which are fueled in part by technological changes, intellectual maturity (or so one thinks), and out-of-the-box thinking that says “surely, there must be a better way”, one dreams of a future. That future consists of many different implications and dimensions, but materially, part of that future consists of devices that compute. These devices are not limited to small gadgets, but include all machinery that makes any kind of decision, whether that decision is autonomous, or imposed by an external act or agent. We dream of a future of endless computation, convenience, and sophistication, orders of magnitude above where we are today.

Limiting the present discussion to non-trivial complex computations, this paper suggests a different paradigm for “intelligent systems” than what is commonly perceived as being sufficient. That paradigm is *Logic Programming*, which is the use of logic to represent and reason about knowledge. Further, this paradigm has been blessed with reasoning formalisms specified in the language of Logic Programming which endow us with the ability to do complicated, human-like reasoning.

These reasoning formalisms that provide incredible reasoning power, include: a well developed theory of multiple forms of negation, an understanding of open domains and the closed world assumption, default reasoning with exceptions, reasoning with respect to time (i.e., a solution to the frame problem, and introspection with regard to previous beliefs), reasoning about actions, introspection about current beliefs (as well as past beliefs), and maintaining multiple

views of the world simultaneously (which enables reasoning with uncertainty.)

This paper suggests that logic programs employing recent advances in semantics and in knowledge representation formalisms provide a more robust framework in which to develop very intelligent systems in any domain of knowledge or application. The author has performed work applying this paradigm and these reasoning formalisms in the areas of financial applications, security applications, and enterprise information systems.

BACKGROUND

This is a primer for computing professionals, and not an authoritative work on the state-of-the-art of Logic Programming. Logic programming presents us with an excellent tool to develop a variety of powerful intelligent systems. What will be discussed is a particular version of logic programming called “ASP”, which means “Answer Set Programming”. “Version” in this context is defined by the semantics of the language, and not by performance issues. ASP is currently the most popular and the most well researched Logic Programming language. (To demonstrate the importance that ASP is receiving in the field, an entire issue of “AI Magazine” has been devoted to ASP. This journal is the flagship journal for the Association for the Advancement of Artificial Intelligence, the premier scholarly and practitioner association in the field of Artificial Intelligence. The issue mentioned is the most current issue at the time of this writing, Volume 37 Number 3, Fall 2016.)

While there are still issues that need to be addressed in Logic Programming, and while

DOI: 10.4018/978-1-5225-2255-3.ch411

there may be additional non-logical techniques to complement logic-based systems, it is reasonable to believe that logic will form the cornerstone of any serious machine intelligence in the future. Consider that the goal of the field of artificial intelligence (in fact, one of the early goals of computing itself) is to build “HAL”, the all-knowing, self-sufficient computer of science-fiction movies (Clarke, 1968). To this end, it behooves us to understand, use, and further refine this paradigm.

In this paper, the syntax and of semantics of ASP shall be presented. The early forms of this language were initially called the Stable Model Semantics, and later, Disjunctive Logic Programming (Gelfond & Lifschitz, 1988; Gelfond & Lifschitz 1991). This language is a purely declarative language (as opposed to procedural languages which dominate industry, and as opposed to functional languages which are the main competitor in the field of AI.) Declarative languages have their roots in logic programming (Kowalski, 1974; Kowalski, 1979), they are defined in the syntax and semantics of standard Prolog (Colmerauer, et. al., 1973; Clark 1978), and they employ the work on nonmonotonic logic (Reiter, 1980; Moore, 1985).

The semantics of ASP are arguably the most well-known and most well-developed semantics in logic programming. That there are other competing semantics is not of concern. Other semantics will differ from the ASP primarily at the extremes. Also, the semantics of ASP are conservative: a system built upon these semantics believes only what it is forced to believe. As already stated, the semantics of ASP are the most popular semantics in the logic programming research community.

It is the hope here that ASP and the accompanying knowledge representation techniques presented will be appreciated by the practitioner community to the extent that ultimately, reasoning systems will be based upon these ideas. The material presented here is self-contained.

ANSWER SET PROGRAMS (ASP)

The language of ASP is mathematically precise, and well understood among researchers and

those “in the know”. A correct discussion of this would necessarily consists of several unambiguous, mathematical definitions. However, for the purposes of this work, definitions will be kept to a minimum, and will favor an intuitive bent, rather than a rigorous mathematical bent. Nonetheless, some formalities are necessary. An intuitive discussion may be viewed as “sloppy” in the sense of mathematical rigor, but it is necessary and easier to understand for those not acquainted with the field. It is this audience to which this paper is being written.

The presentation here will be “backwards” in the sense of starting with the final result, and explaining the component pieces. A mathematical presentation would do the opposite: build a foundation, such that when the final result is presented, all the pieces have already been discussed.

Syntax

The syntax of any language is the grammar that defines how to construct legal sentences in that language. The syntax of ASP is as follows. A rule (the only building block of an ASP program) is of the form:

$$l_0 \text{ or } \dots \text{ or } l_i \leftarrow l_{i+1}, \dots, l_m, \text{ not } l_{m+1}, \dots, \text{ not } l_n \quad (\text{Gelfond \& Kahl, 2014})$$

where the l s are “literals”, $i \geq 0$, $m \geq 0$, and $n \geq 0$.

The symbol l is just an abstraction for a “predicate” with the “terms” appropriate for that predicate. (All these predicates and terms are defined merely by their use in an ASP program.) These would be some examples of literals:

```
male(john)
married(john, sue)
employee(john, accounting, 1/25/2012)
itIsHotToday()
```

The terms of the last two literals need further technical explanation, but suffice it to say that even these literals *could* be correct.

The left side of the ‘ $\leftarrow$ ’ symbol is called the “head” of the rule, and the right side of that symbol is called the “body” of the rule. This is a rule of inference: if the right side of the rule is true, then the left side of the rule must be true. (That is, the head can be inferred to be true.) There can be zero or more literals on the left side of the ‘ $\leftarrow$ ’ symbol; there can be zero or more literals in the part of the body prior to the sequence of “not” symbols; and there can be zero or more literals each individually preceded by the symbol “not”.

The above examples of literals only tell part of the story. Those literals are “positive”. In a proper context, they could be making the claim that something is true. (For instance, that it is true that “john” is a “male”.) There are also “negative” literals. For instance

$\neg$ married(john, sue)

in the proper context, could be stating that it is true that *john* and *sue* are not married. (Perhaps this should be stated more strongly: it is absolutely false that *john* and *sue* are married.) The symbol $\neg$ is called “strong negation”. A literal can be positive or negative.

The symbol “not” means that something is “unknown”. Mathematically, it means that something is “unprovable”. According to the rules of the specific ASP program, it can not be proven to be true. This symbol is called “weak negation”.

Semantics

The syntax of a language describes how to construct legal sentences in that language. The semantics of that language describe what those sentences mean.

As a prelude, the notion of *satisfiability* needs to be discussed. The ultimate goal is to arrive at an *answer set* for a program. All interactions with a program (queries about whether or not something is true) will be made with respect to this answer set. This answer set is a minimal set of literals that *satisfies* the rules of the ASP program. The following is the definition of satisfiability.

“A set S of ground literals **satisfies**:

1. l **if** $l \in S$;
2. $\text{not } l$ **if** $l \notin S$;
3. $l_0 \text{ or } \dots \text{ or } l_n$ **if** for some $1 \leq i \leq n$, $l_i \in S$
4. a set of ground extended literals **if** S satisfies every element of this set;
5. rule r **if**, whenever S satisfies r ’s body, it satisfies r ’s head.” (Gelfond & Kahl, 2014, p. 15)

A “ground literal” is a literal in which there are no variables. For instance,

male(john)

is a ground literal, whereas

male(X)

is not.

A “ground extended literal” is a ground literal that optionally may or may not be preceded by the symbol “not”, such as

not visiting(john, sue).

If set S from above satisfies all the rules of the ASP program, and if set S is minimal (with respect to set inclusion, meaning that there is not proper subset of S which also satisfies all the rules of the ASP program), then S is an answer set for the program. It may be possible to have more than one answer set for a program. (Multiple answer sets can be induced either by: 1) weak negation (the “not” symbol), or 2) a head in which disjunction (the “or” symbol) appears. There are ways to ensure that there exists only one answer set, but that discussion is beyond this paper.

In its simplest, abstract sense, the goal of any program is to answer queries. To “run the payroll”, what is being asked is “What is the net pay of each employee for this pay period”. Different questions might include things such as “what is John’s wife’s name”, “should the A/C be turned on

to maintain a temperature of 78 degrees”, “should I shoot down the incoming missiles”.

Let us consider a query *Q* which is a literal. In determining how an ASP program responds to that query, the answer is:

1. *Yes*, if *Q* is an element of ALL the answer sets of the program
2. *No* if the complement of *Q* is an element of ALL the answer sets of the program
3. *Unknown* otherwise

This discussion of semantics has omitted some important aspects, namely:

1. The semantics of a program that includes disjunctive heads (the notion of an answer set being minimal necessitates that when required, and whenever possible, only one disjunct of that head is an element of the answer set),
2. The meaning of query *Q*, when *Q* is a conjunctive query (each element of the conjunction must be true with respect to All the answer sets for the query to be true, or at least one element is false with respect to ALL the answer sets for the query to be false, unknown otherwise), and
3. The meaning of query *Q*, when *Q* is a disjunctive query (only one element of the query needs to be true in ALL the answer sets for the query to be true, or each element of the disjunction must be false in ALL the answer sets for the query to be false, unknown otherwise.)

Some Reasoning Techniques

Defaults with Exceptions

Default reasoning is a key area of human mental activity. Simply put, default reasoning is “jumping to a conclusion”. Throughout any typical

day, a human will jump to many conclusions. It is this area of reasoning that differentiates between human reasoning and mathematical logic. Mathematical logic is “sound and complete”. “Soundness” means that a conclusion is correct under all circumstances. New information will not change the truth of such a conclusion. “Hunches”, on the other hand (which humans are so good at) are not sound conclusions. The conclusions may ultimately be right, or they may turn out to be wrong. Yet, without “hunches” or “jumping to conclusions”, people could not operate. Humans do not live in this world with complete knowledge, therefore, much of the time we are guessing.

This is an area of reasoning that has proven difficult for computers. Work in this area originated with (Reiter, 1980). In the context of logic programming, it is more clearly understood with the work of (Gelfond, 1994).

As an example, assume *sam* is a bird. Let us decide if *sam* flies. This is formalized as

```
flies(X) ←
bird(X), (3)
not ab(flies, bird, X), (4)
not ¬flies(X). (5)
```

Line (5) is necessary to prevent our program from concluding an inconsistency. It is not desired for the program to conclude that a specific bird flies if it can elsewhere conclude that that same bird does not fly.

Line (4) is a crucial part of the formalism. *Ab* is called the *abnormality predicate*. It is a 3-ary predicate. Its use is to state that something is abnormal. The first term is the predicate which we are trying to conclude, in this case, *flies*. The second term is the predicate which states that “normally, *X*’s are *Y*’s”. In this case, that predicate is *bird*. The statement is that normally, birds fly.

Line (3) lists all the “normal” criteria for concluding the head of the rule. The entire rule reads: “if *X* is a bird, and if it is not known that

X is abnormal with respect to flying, and if it cannot be concluded that X does not fly, then it is concluded that X flies.

In this example, given just the rule above, and the fact

bird(sam)

then it can be concluded that *sam* flies.

Let us expand the example by adding the following information:

penguin(sam)
ab(flies, penguins, X)

These rules state that *sam* is a penguin, and that penguins are abnormal with respect to flying. Now, our program will not conclude that *sam* flies.

In order to allow our program to jump to safe conclusions, we create such defaults rules. We then must also list the conditions under which the defaults are abnormal. This is a very modular approach.

(Zhang 2003) presents the notion of having priorities among defaults. Not only does this allow us to express a hierarchy of defaults, but can also ensure a unique answer set, which greatly simplifies computation.

Selectively Implementing CWA

CWA (the “closed world assumption”) is appropriate in applications for which it is appropriate to assume that the reasoner has complete knowledge. Such an application would be an airline schedule. If we ask the reasoner if there is a 3:00 flight from Dallas to Chicago on Friday, the answer is easily determined. If there exists a record in the flight table for such a flight, then the answer is yes (equivalently, true.) Otherwise, it is false that such a flight exists.

CWA assumes that you have complete knowledge of the domain you are reasoning about. For some applications (such as an airline schedule), this is appropriate. For other applications, this is

disastrous. What we need, and what we illustrate here, is the ability to selectively incorporate CWA. (That is, to use it when it is needed, and to not use it when it is not needed.) Consider a human resources database that defines the *employee* relation with rules of the form:

employee(john, accounting, 40000)

which states that *john* is an employee who works in the *accounting* department, earning a salary of \$40,000. Suppose we ask the query

employee(mary, X, Y)?

which asks whether or not *mary* is an employee. Suppose that this person does not work for our company, and therefore, such a fact is not in the database. Since neither the query nor its negation can be proven, the result would be *unknown*. However, this does not match normal intuition. In this scenario, it is clearly desired that the system respond to such a query with “no”.

The desired result can be achieved by applying CWA to the *employee* relation. This can be done with the following rule:

$\neg employee(X, Y, Z) \leftarrow$
not employee(X, Y, Z)

This rule means that if it is not believed that X is an employee, then it is definitively false (by way of default reasoning) that X is an employee. For every predicate (or relation) for which CWA is desired, such a rule very similar to the above needs to be added.

Reasoning About Actions and Time

A very significant area of knowledge representation (especially as it relates to logic programming) is reasoning about actions and time. (Baral, et. al., 1997a; Baral & Gelfond, 1997b; Gelfond & Lifschitz, 1993) formalize these ideas in extended logic programs.

At first glance, it may appear that reasoning about actions is an irrelevant exercise. However, all computer processing can be formalized in this framework. Any entity can be abstracted as an agent. Agents perform actions. Any event can be abstracted as an action. Actions cause information to change. (Things may become true or false due to an action.) Within a theory of actions, information is represented as *fluents*. Any piece of information can be abstracted as a fluent. A theory of actions can be used to represent any area of human knowledge, or any area of human endeavor.

A fluent is defined as in the following.

fluent(Type,Item).

This formula has two parameters (terms). The first parameter identifies the type of fluent. There are two values for the type of fluent: *i* means the fluent is inertial, and *n* means the fluent is not inertial. An inertial fluent retains its value from one time period to the next, unless an action causes its value to change. A non-inertial fluent retains its value only for the present time period (or the present duration of time, whichever is appropriate.) The second parameter *m* identifies the fluent itself. Consider the following example. *fluent(i,m)*

In this example, suppose that *m* is a message which means “the books are out of balance”. It is an inertial fluent, meaning that if the books are out of balance, they will remain out of balance until something happens to change that fact. On the contrary, if the books are not out of balance (meaning they are balanced), then they will remain balanced until something happens to change that fact. This fluent (or proposition) can be true, false, or unknown.

Assume that the truth value of this fluent is “true”. Since the fluent is inertial, it will remain true that the books are out of balance until something causes it to change its truth value. An example of something that could cause it to change its truth value would be the action of making a journal entry to balance the books. Another example of

something which could change the truth value of this fluent is that the error causing the imbalance could be discovered and corrected.

What causes this fluent to have any meaning at all is an assertion as to whether the fluent is true or not. It is the collection of these assertions which form our knowledge base, or our set of beliefs. The general form for such an assertion is *holds*(*Fluent*, *Time*, *Truth_vale*).

Hence, *holds(m,1005,0)* means that fluent *m* is *false* at time 1005. (To relate this back to our example, “it is explicitly false that the books are out of balance at time 1005”.) Similarly, *holds(m, 1005, 1)* means that fluent *m* is *true* at time 1005. A fluent does not ever have to be asserted as either true or false; it could be “unknown”. There is not a separate designation for “unknown”. Rather, both formulae *holds(m,1005,0)* and *holds(m, 1005, 1)* would be missing from our set of beliefs.

A powerful feature of fluents is that unlike other variables in typical programming languages, a fluent can have very many values. The value of interest is determined by the context of time. Assume that we have the formula *holds(m, 1005, 1)*. Since this fluent is inertial, it will remain true the next time period, unless something happens to change that fact. Therefore, we will also have *holds(m, 1006, 1)*. We will continue to have similar formulae for each time period until the value of the fluent changes. Suppose that quite some time later at time period 2233, an action causes the books to become “balanced”. We will have the formula *holds(m, 2233, 0)*. Suppose that a very long time later at time period 102054321, the books became out of balance again. We will then have the formula *holds(m, 102054321, 1)*. A year later, we have all this knowledge available to us, and we can determine that at time period 1005 the books became out of balance, they remained out of balance until time period 2233, and they remained balanced from time period 2233 until time period 102054321.

To give a more complete picture of a theory of actions, there are underlying rules of significance. Some of those rules define the “law of inertia”.

What this means is that there are rules that infer that if an inertial fluent held in one time period, it will continue to hold the next time period unless something changes that fact. There are also rules that define the actions of the domain being reasoned about. In particular, those rules will define the impact of actions. For instance, if I turn on a light with paint on my finger, it will then be true that the light is on, it will be true that I can see what I am doing, it will be true that there is paint on the light switch, it will be true that the nocturnal insects are scurrying for cover, etc.

Other Knowledge Representation Issues

There are many other knowledge representation issues which have been identified, carefully analyzed, and formalized. (Baral, 2003; Brachman et.al., 2004; Davis, 1990), and to a lesser extent (Genesereth, et. al., 1987) address many of these. Some of the issues they identify are generic and apply to any domain of reasoning. Others are domain specific. The latter three books (i.e., all except (Baral, 2003)) represent the ideas in *first order logic* (FOL). Formulae in FOL would have to be translated into logic programs.

FUTURE RESEARCH DIRECTIONS

Further Development of Recent Research

There are several ideas found in recent research worthy of deeper consideration. These may assist in tailoring systems which are either more correct, or better suited to serve a particular reasoning constraint. (Delgrande, et. al., 2003; Eiter, et. al., 2003) discuss how to give preference among rules. This would be objectionable to a “purist” view, since a logician would take the posture that we are concerned about all that a program entails.

Nevertheless, this is very much akin to what happens in conflict resolution of rule-based systems. Further, as will be pointed out in a moment, this approach lends itself to creating a unique (i.e., single) answer set.

An inconsistent program is one that infers P and $\neg P$, for some atom P . We mentioned earlier how to cast default rules so that the default rules themselves will not introduce an inconsistency. There may be other opportunities for inconsistencies to be introduced. (Nieuwenborgh and Vermeir, 2006) find the “best” answer set for such programs. (Balduccini & Gelfond, 2003) take another approach. They have developed *CR-Prolog* which restores consistency in answer set programs (without sacrificing multiple answer sets, as the “best” answer set approach does.)

Answer set programming allows us to represent uncertainty with its ability to represent multiple views of the world, and with its semantics for negation as failure. To further our ability to represent and reason about uncertainty, (Baral, et. al., 2004) introduces the concept of combining answer set programming with probabilistic reasoning. This paradigm is called *P-log*. (Gelfond, et. al., 2006) combines the consistency restoring abilities of *CR-Prolog* with the probabilistic features of *P-log*.

Implementation Issues

An implementation issue is the software platform (akin to a “compiler”) to use. In short, we are faced with two choices: use a commercial Prolog product, or use a research tool. The advantages of using a commercial product are many. Some of these include: a wide user-base, an efficient product, an easy-to-use interface, product stability, etc. However, the most compelling disadvantage is that a Prolog product limits the representation and reasoning abilities. On the other hand, a research tool (such as *SModels*) implements the full features of extended logic programs. (In fact, it implements the full features of disjunctive

logic programs, which is higher in the hierarchy.) Each of the advantages of a commercial product is a disadvantage for a research tool.

The criteria for selecting a commercial product vs. a research tool is simple: is the ability to represent multiple ways of viewing the world more important than all the benefits of a commercial product? We live in such a monolithic world (in terms of information processing) that in many cases the answer will be “no”. Hence, the choice in these situations would be a commercial Prolog product. To make this choice does not mean to entirely negate the power of logic programming. The companion paper mentioned before discusses several knowledge representation techniques. If the product implements negation as failure, and if designers/users can accept a monolithic view of the world (which to this point, they have), then expert systems can still be advanced by implementing the sophisticated representation methodologies of the companion paper. On the other hand, for the truly adventurous, the use of the full power of the language of extended logic programs in an environment that truly supports the language (such as SMOBELS) will provide reasoning abilities far beyond current practice (albeit, at the price of a clumsy interface.)

CONCLUSION

We see logic programming to be a viable, more powerful, and more robust alternative to both traditional expert systems technology, and typical Prolog systems. Acceptance of this paradigm, and its associated reasoning paradigms, will advance any field of computing which desires to achieve some form of robust intelligence. Systems based upon these ideas will be capable of far more complex reasoning.

The ASP is a powerful, popular semantics in the field of logic programming. A challenge for the practitioner would be to decide how to implement this language. The practitioner is faced with

two basic choices: either implement a subset of the language in a commercially available Prolog product or implement the full language in one of the newer tools coming to market (which likely would be the immediate successor of a research tool that is not very user-friendly.)

KEY TERMS AND DEFINITIONS

Artificial Intelligence: The field of research aimed at getting a computer to perform tasks which one would normally associate with intelligence. Mathematician Alan Turing proposed what is now called “the Turing test” to define artificial intelligence. Loosely speaking place a computer in one secluded room, and a human in another secluded room. If an observer queried these two entities, and could not identify which entity was

the computer, then the computer had achieved intelligence on a par with a human.

Atom: Consists of an n-ary predicate symbol and n-terms. An example would be married(john,sue).

Common Sense Reasoning: A field of research in the artificial intelligence community that seeks to endow a computer with “common sense”. Many applications of artificial intelligence are highly successful. As an example, consider the fact that IBM’s “Big Blue” has defeated the world chess champion on multiple occasions. Yet, all computer applications perform miserably when required to perform outside of the realm for which they were designed. Put differently, the performance of humans degrades gracefully, while the performance of computers plummets rapidly when performing unanticipated tasks.

Extended Literal: A literal possibly preceded by the logical connective “not”. All of the following are extended literals - male(john), $\neg$ male(john), not male(john), not $\neg$ male(john).

Ground: There are no variables for a term; all terms are object constants. For instance, male(X) is not ground, but male(john) is ground. ‘X’ is a variable. ‘john’ is an object constant.

Knowledge Representation: A field of research within artificial intelligence that seeks to methodically identify ways in which to represent and reason about knowledge of a particular domain.

Literal: An atom or its negation. Examples would be married(john,sue), or $\neg$ married(john,sue).

Logic Programming: A field of research within artificial intelligence that seeks to use logic to represent and reason about knowledge. Initially, pure mathematical logic was used (aka “first order logic”). However, as the need to mimic human thought processes became prevalent (such as “rules of thumb”, or “jumping to conclusions”), the field broke away from first order logic. The field still has a very strong relationship to first order logic. However, the field employs nonmonotonic techniques, and higher orders of logic.

Strong Negation: Use of the ‘ $\neg$ ’ connective. This connective means “it is absolutely false that...”.

Weak Negation: Use of the “not” connective. This connective means “it is not provable that...”.

Methods for Improving Alias Rejections in Comb Filters

Gordana Jovanovic Dolecek

Institute INAOE Puebla, Mexico

INTRODUCTION

Decimation is the process of decreasing the sampling rate by an integer M in the digital domain. This process is used in sub band coding, filter banks, communication systems, oversampled A/D (analog/digital) converters, among others. If the signal is not appropriately filtered, the unwanted replicas of the main spectrum of the decimated signal, called aliasing, will be present. Therefore, to prevent aliasing in the decimated signal, the signal must be first filtered by a low pass filter, called anti-aliasing, or decimation filter. As a result, the process of decimation consists of two principal stages: filtering and down sampling (decreasing the sampling rate by integer M). The integer value M is also called the decimation factor.

In order to avoid high order decimation filters, the decimation is usually performed in two or more stages. The most simple decimation filter is comb filter, (Hogenauer, 1981) which usually works at high input rate. The transfer function of the comb filter is given as:

$$H(z) = \left[\frac{1}{M} \frac{1 - z^{-M}}{1 - z^{-1}} \right]^K, \quad (1)$$

where K is the order of the comb, and z is a complex variable.

The magnitude characteristic of the comb filter, expressed in digital frequency ω , is given as:

$$|H(e^{j\omega})| = \left| \frac{1}{M} \frac{\sin(\omega M / 2)}{\sin(\omega / 2)} \right|^K. \quad (2)$$

The magnitude characteristic must be flat in the pass band of interest. Additionally, in order to eliminate aliasing, the comb filter must have a high attenuation in the so called folding bands, which are the bands around the zeros of the comb filter.

BACKGROUND

A simple method to increase the attenuation in the comb folding bands consists of increasing the order of the comb filter, as shown in Figure 1. Here, the decimation factor M is 10 and the values of order K are 1, 3, and 5. The zooms in the pass bands in Figure 1 show that the pass band droop increases with the increase of the order of the comb filter.

The objective of this article is to present the methods proposed so far to increase the bandwidths around the comb zeros, and thus increase the comb alias rejection.

Methods for increasing comb alias rejections are primarily based on comb zero rotation. Additional methods based on cosine filters, Chebyshev polynomials, cyclotomic polynomials, and cascade of combs with different decimation factors, among others, are also used in practice.

REVIEW OF THE METHODS BASED ON COMB ZERO ROTATION

Zero Rotation

The comb zero rotation was introduced by (Presti, 2000). The method consists of applying a clock-

Figure 1. The overall comb magnitude characteristics and the pass band zooms for $M=10$ and different filter orders

wise rotation of β radians to any zero of comb filter, thus obtaining the following transfer function:

$$H_u(z) = \frac{1}{M} \frac{1 - z^{-M} e^{j\beta M}}{1 - z^{-1} e^{j\beta}}. \quad (3)$$

By applying the rotation in the reverse direction, the following transfer function is obtained:

$$H_v(z) = \frac{1}{M} \frac{1 - z^{-M} e^{-j\beta M}}{1 - z^{-1} e^{-j\beta}}. \quad (4)$$

The filters (3) and (4) both have complex coefficients. However, their cascade has real coefficients:

$$\begin{aligned} H_r(z) &= H_u(z) H_v(z) \\ &= \frac{1}{M} \frac{1 - z^{-M} e^{j\beta M}}{1 - z^{-1} e^{j\beta}} \frac{1}{M} \frac{1 - z^{-M} e^{-j\beta M}}{1 - z^{-1} e^{-j\beta}} \\ &= \frac{1}{M^2} \frac{1 - 2 \cos(\beta M) z^{-M} + z^{-2M}}{1 - 2 \cos(\beta) z^{-1} + z^{-2}} \end{aligned} \quad (5)$$

Figure 2(a) shows the zeros of a comb filter with $M=5$ and $K=1$. Similarly, Figure 2(b) shows the rotated zeros from (5), taking $\beta=0.03$. Note that the zeros of (5) are rotated around the original comb zero positions.

The cascade of the filter (5) and the comb filter is called rotated sinc (RS) filter:

$$\begin{aligned} H_R(z) &= H(z) H_r(z) \\ &= \frac{1}{M} \frac{1 - z^{-M}}{1 - z^{-1}} \frac{1}{M^2} \frac{1 - 2 \cos(\beta M) z^{-M} + z^{-2M}}{1 - 2 \cos(\beta) z^{-1} + z^{-2}} \end{aligned} \quad (6)$$

Figure 3 compares the magnitude responses of a comb filter with parameters $M=5$, $K=3$ and the corresponding RS filter. The first folding band zooms are also shown.

It can be observed that due to the rotated zeros, the RS filter provides wider folding bands and consequently has better aliasing rejection than the corresponding comb filter and without additional deterioration in the pass band region. The method

Figure 2. Pole-zero plots (a) Comb filter, $M=5$, $K=1$. (b) Filter (5), $M=5$, $\beta=0.03$

is generalized in (Laddomada, 2007) wherein a generalized comb filter (GCF) is introduced in which the parameter β is optimized to achieve

the optimal alias rejection for a given M and K . However, the comb zeros rotation introduces some problems, discussed in next section.

Figure 3. Magnitude responses of comb filter $M=5$, $K=3$ and the corresponding RS filter

Problems

The comb zero rotation improves the comb alias rejection but in turns introduces the following problems:

- Two multipliers are introduced, one working at high input rate.
- There is possible instability due to loss of pole-zero cancellation on the unit circle, in the case of the finite precision of coefficients.
- The most important first comb folding band has less attenuation than other folding bands and also has the worst case aliasing occurs.

As it mentioned before, the popularity of comb decimation filter is due to its simplicity, (comb filter is a multiplier less filter). Consequently, introducing multipliers for improvement of its characteristic degrades its principal features. As a result, it is desirable that the filter used to improve comb filter characteristic be also a multiplierless filter.

The solution to avoid possible instability is to eliminate the poles on the unit circle using a non recursive form for the rotation term.

Different methods have been proposed to solve above mentioned problems. In the following are presented some of the methods based on comb-zero rotation

1. Method in (Jovanovic Dolecek & Mitra, 2004)

In (Jovanovic Dolecek & Mitra, 2004), a modification of the original comb zero rotation method was proposed for the case in which the decimation factor M is a product of two integers M_1 and M_2 : $M = M_1 M_2$. To this end, the modified comb decimation filter has two stages with the different filter orders K_1 and K_2 :

$$H_m(z) = \left[\frac{1}{M_1} \frac{1 - z^{-M_1}}{1 - z^{-1}} \right]^{K_1} \left[\frac{1}{M_2} \frac{1 - z^{-M_2}}{1 - z^{-M_1}} \right]^{K_2} = H_1(z) H_2(z^{M_1}) \quad (7)$$

The filter $H_2(z^{M_1})$ can be moved to a lower rate which is M_1 times less than the high input rate, becoming:

$$H_2(z) = \left[\frac{1}{M_2} \frac{1 - z^{-M_2}}{1 - z^{-1}} \right]^{K_2} \quad (8)$$

Next, the zero rotation is applied only to the comb $H_2(z)$, resulting in the following modified rotated term:

$$H_{rm}(z) = \frac{1}{M^2} \frac{1 - 2 \cos(\beta M) z^{-M} + z^{-2M}}{1 - 2 \cos(\beta M_1) z^{-M_1} + z^{-2M_1}} \quad (9)$$

The transfer function of the modified RS filter is given as:

$$H_{Rm}(z) = H_m(z) H_{rm}(z) = H_1(z) H_2(z^{M_1}) \frac{1}{M^2} \frac{1 - 2 \cos(\beta M) z^{-M} + z^{-2M}}{1 - 2 \cos(\beta M_1) z^{-M_1} + z^{-2M_1}} \quad (10)$$

In contrast to the original rotated term (5), the rotated term in (9) works at rate which is M_1 times less than the high input rate. This price is that not all folding bands are improved, as shown in Figure 4, where the modified RS filter is compared with the original RS filter using $M=8$, $K=2$, $M_1=2$, $M_2=4$, $K_1=2$, $K_2=1$, and $\beta=0.03$.

The method is generalized in (Jovanovic Dolecek & Mitra, 2005) for the multistage comb decimator.

Figure 4. Comparison of magnitude responses of the RS and the modified RS filters

2. Method in (Jovanovic Dolecek, 2010)

In order to improve the alias rejection in the first folding band and to eliminate possible instability, the method proposed in (Jovanovic Dolecek, 2010) applies the zero rotation only in the first folding band, yielding:

$$\begin{aligned} H_{ZR}(z) &= k(1 - z^{-1}e^{-j\beta})(1 - z^{-1}e^{j\beta}) \\ &= k(1 - 2\cos(\beta)z^{-1} + z^{-2}), \end{aligned} \quad (11)$$

where k is the normalizing constant introduced to ensure that the magnitude characteristic is equal to 1 at $\omega = 0$.

The transfer function of the modified comb is given as

$$H_m = \left[\frac{1}{M} \frac{1 - z^{-M}}{1 - z^{-1}} \right]^K k \left(1 - 2z^{-1} \cos \left(\frac{2\pi}{M} - \frac{\pi}{(\beta_o + 2)M} \right) + z^{-2} \right), \quad (12)$$

where β_o is chosen to ensure that the rotated zeros are in the first folding band, $\beta_o = 0.99$.

To improve the alias rejection in subsequent folding bands, the expanded cosine filters are cascaded with the modified comb (12):

$$H_{\cos}(z) = \prod_{i=1}^{M/2} \left[\frac{1}{2} (1 + z^{-N_i}) \right]^{K_1}. \quad (13)$$

As a result, the following modified comb transfer function is obtained:

$$H_{m\cos}(z) = H_m(z)H_{\cos}(z). \quad (14)$$

Figure 5 compares the magnitude responses of the filter (14) and the comb filter for $M=12$, $K=4$, $N_i=1$, taking $i=1, \dots, 6$, and $K_1=1$.

Figure 5. Comparison of the magnitude responses of the RS and the modified cosine filter

3. Method in (Jovanovic Dolecek & Fernandez-Vazquez, 2010)

In (Jovanovic Dolecek & Fernandez-Vazquez, 2010) a method is presented wherein, the rotation term is expressed in a non recursive form, thus avoiding the possible instability due to the loss of pole-zero cancellation on the unit circle:

$$H_{r,nr}(z) = \frac{1}{M^2} \left[\sum_{i=0}^{M-2} c_i (z^{-i} + z^{-(2M-2-i)}) + c_{M-1} z^{-(M-1)} \right], \quad (15)$$

where

$$c_i = 2 \cos(\beta) c_{i-1} - c_{i-2}, \quad i = 0, \dots, M-2, \\ c_0 = 1; c_1 = 2 \cos(\beta). \quad (16)$$

Note that the filter (15) is symmetric and consequently has linear phase. The number of coefficients in (15) is equal to $M-1$.

As one example, using $M=5$, and $\beta=0.03$ in (16) the coefficients c_i are obtained as follows:

$$c_1=1.9991; c_2=2.9964; c_3=3.9910; c_4=4.9820. \quad (17)$$

The corresponding rotated term (15) is given as:

$$H_{r,nr}(z) = \frac{1}{25} \left[\begin{aligned} &(1 + z^{-8}) + 1.9991(z^{-1} + z^{-7}) \\ &+ 2.9964(z^{-2} + z^{-6}) \\ &+ 3.9910(z^{-3} + z^{-5}) + 4.9820z^{-4} \end{aligned} \right]. \quad (18)$$

It can be observed that this filter is equivalent to the recursive filter (5) for $M=5$ and $\beta=0.03$, and being in the non recursive form does not suffer from possible instability.

Using the rotation term (15), the transfer function of the corresponding RS filter is obtained as:

$$H_{RS} = H(z)H_{r,nr}(z). \quad (19)$$

Figure 6. Comparison of magnitude responses of the RS and the rounded non recursive RS filters

Note that this filter requires multipliers.

To eliminate the presence of multipliers, the method proposed in (Jovanovic Dolecek & Fernandez-Vazquez, 2010) rounds the coefficients c_i using the rounded constant $r=2^k$:

$$C_i = r \text{ round}(c_i/r), \quad (20)$$

where $\text{round}(x)$ means rounding of x to the nearest integer.

As a result of the rounding of the coefficients in (15), the following transfer function is obtained:

$$H_{r,nrr}(z) = A \left[\sum_{i=0}^{M-2} C_i (z^{-i} + z^{-(2M-2-i)}) + C_{M-1} z^{-(M-1)} \right], \quad (21)$$

where C_i can be implemented as adds and shifts, thus resulting in a multiplierless filter, and A is the normalization constant.

The rounded RS filter is given as:

$$H_{RSr} = H(z)H_{r,nrr}(z). \quad (22)$$

The rounding introduces a small distortion of the magnitude response. The level of the distortion is determined by the rounding constant.

As an example, by considering $r=2^6$ the following integer coefficients C_i in (21) are obtained from (17):

$$C_1=r128; C_2=r192, C_3=r255, C_4=r319. \quad (23)$$

Figure 6 compares the magnitude responses of RS and rounded non recursive RS filters, for $M=5$ and $\beta=0.03$, using $r=2^6$.

The principal problem in this method is a high number of coefficients which increase with the increase of the value of M . Similarly, in the rounded case, the number of adders is high and increases with the increase of the decimation factor M . As a result, the method is convenient only for small values of M .

4. Method in (Jovanovic Dolecek & Laddomada, 2015)

The problem of the increased number of the coefficients is solved by proposing a two-stage comb structure where the rounded rotation term is applied only at the second stage. Considering $M=M_1M_2$, the rotation term is given as:

$$H_{r, nr2}(z) = \frac{1}{M_2^2} \left[\sum_{i=0}^{M_2-2} c_i (z^{-i} + z^{-(2M_2-2-i)}) + c_{M_2-1} z^{-(M_2-1)} \right], \quad (24)$$

where the coefficients c_i are computed using (16) taking M_2 instead of M .

Note that as in (16), the coefficients c_i do not depend on the M but only on the rotation angle β .

The filter (24) has (M_2-1) coefficients which is less than in method (Jovanovic Dolecek & Fernandez-Vazquez, 2012), which requires $M-1$ coefficients.

The modified RS filter has the following transfer function:

$$H_{mRS}(z) = [H_1(z)]^{K_1} [H_2(z^{M_1})]^{K_2} H_{r, nr2}(z^{M_1}). \quad (25)$$

As an example, by considering $M=8$ and $M_1=2$, $M_2=4$, and $\beta=0.25$ we have

$$\begin{aligned} H_{r, nr2}(z) &= \frac{1}{16} \left[\sum_{i=0}^2 c_i (z^{-i} + z^{-(8-2-i)}) + c_3 z^{-3} \right] \\ &= \frac{1}{16} \left[(1 + z^{-6}) + c_1 (z^{-1} + z^{-5}) + c_2 (z^{-2} + z^{-4}) + c_3 z^{-3} \right], \end{aligned} \quad (26)$$

where

$$c_1 = 2 * \cos(0.25) = 1.9378.$$

$$c_2 = 2 * c_1 * \cos(0.25) - 1 = 2.7552. \quad (27)$$

$$c_3 = 2 * c_2 * \cos(0.25) - c_1 = 3.4012.$$

Note that here one needs only 3 coefficients, while in the method in (Jovanovic Dolecek, Fernandez-Vazquez, 2012) one needs 7 coefficients. Figure 7 compares magnitude responses of the filter (25) and the comb filter. (Parameters of the filter (25) and comb are: $M_1=2$, $M_2=4$, $K_1=2$, $K_2=1$, and $M=8$, and $K=2$, respectively).

Note that all folding bands are improved except for the last folding band. Similar to the method in (Jovanovic Dolecek & Fernandez-Vazquez, 2012), the coefficients c_i can be rounded, thus obtaining the multiplierless filter.

REVIEW OF METHODS BASED ON DIFFERENT CONCEPTS

Cosine Filters

The special case of comb filter for $M=2$, is a so-called cosine filter:

$$H(z) = \frac{1}{2} \frac{1 - z^2}{1 - z^{-1}} = \frac{1}{2} (1 + z^{-1}). \quad (28)$$

The name cosine is due to the cosine form of the magnitude response of the filter (28):

$$|H(e^{j\omega})| = \cos(\omega / 2). \quad (29)$$

The expanded (by integer N) filter is obtained by replacing each delay z^{-1} by z^{-N} . From (28), the transfer function of the expanded cosine filter is given as:

$$H(z^N) = \frac{1}{2} (1 + z^{-N}). \quad (30)$$

From (29), the magnitude response of the expanded cosine filter is given as:

Figure 7. Comparison of magnitude responses of the comb and the two-stage non recursive RS filters

$$|H(e^{jN\omega})| = \cos(N\omega / 2). \quad (31)$$

By properly choosing the integer N , the zeros of the expanded cosine filter may fold down into the comb folding bands, and thus increase comb alias rejection.

1. Method in (Jovanovic Dolecek & Laddomada, 2013)

The cascade of two expanded cosine filters is proposed. The transfer function is given as:

$$H_{\cos}(z) = \frac{1+z^{-N_1}}{2} \frac{1+z^{-N_2}}{2}, \quad (32)$$

where N_1 and N_2 are integers.

The magnitude response of (32) is given as:

$$|H_{\cos}(e^{j\omega})| = |\cos(\omega N_1 / 2) \cos(\omega N_2 / 2)|. \quad (33)$$

The parameters N_1 and N_2 depend on the value of the decimation factor M . The parameters N_1 and N_2 are chosen to get zeros on the left and right sides of the first comb zero, respectively. There are two cases depending if M is even, or odd.

$$M \text{ even} : N_1 = \frac{M}{2} - 1; N_2 = \frac{M}{2} + 1. \quad (34)$$

$$M \text{ odd} : N_1 = \left\lfloor \frac{M}{2} \right\rfloor; N_2 = N_1 + 1. \quad (35)$$

The cosine-based comb filter is obtained by cascading the comb and cosine filters (32):

$$H_{\text{comb-cos}}(z) = A \left[\frac{1-z^{-M}}{1-z^{-1}} \right]^K (1+z^{-N_1})(1+z^{-N_2}). \quad (36)$$

Figure 8. Magnitude responses of the comb filter, cosine filter and comb-cosine filter

As an example consider comb filter with $M=12$ and $K=3$. According to (34), the corresponding values for N_1 and N_2 are 5 and 7, respectively. Figure 8 presents the magnitude responses of the comb filter, cosine filter (32) and comb-cosine filter (36). Note that, due to the cosine filter, the comb first folding band is wider and has an increased attenuation. However, not all folding bands are equally improved. Best improvements are obtained in the first and fourth folding bands.

2. Method in (Garcia Robles & Jovanovic Dolecek, 2016)

This paper describes novel, low complexity non-recursive comb-cosine decimation structures for decimation factors which can be presented as a power of two. The alias rejection is improved by inserting cosine filters into a certain stage of a comb non-recursive structure. The position of

cosine filters in the structure results in a trade-off between the improvement of alias rejection and area and power consumption.

Chebyshev Polynomials

The stop bands of a comb decimation filter can be improved by sharpening with a Chebyshev polynomial, using a previously reported comb variant. As a result, comb multiple zeros are separated into an equiripple stop band.

1. Method in (Coleman 2012)

The method uses the sharpening comb with a Chebyshev polynomial. The advantage of the Coleman's method is that the same controlled attenuations and widths across all folding bands are obtained.

Figure 9. Magnitude responses of the Coleman's comb filters. (a) Minimum attenuations: 100dB. (b) Minimum attenuations: 120dB

As an example, consider $M=16$ and the 5th degree Chebyshev polynomial $T_5(x)=5x-20x^2+16x^5$. Figures 9(a) and 9(b) show the magnitude responses of the Coleman's comb filters for two values of the minimum attenuations: 100dB, and 120dB.

Cascade of Combs with Different Decimation Factors

The cascade of comb filters of different orders and with different decimation factors may result in higher attenuation than the equivalent comb filter.

1. Method in (Stosic, Milic & Pavlovic, 2015)

Considering the equivalent comb filter of order $7L+3$, where L is a given integer, and the decimation factor M , the following cascade is proposed:

$$H_{\text{cascad_comb}}(z) = [H_1(z)]^{L+1} [H_2(z)]^{L+1} [H_3(z)]^{L+1} [H_4(z)]^L [H_5(z)]^L [H_6(z)]^L [H_7(z)]^L, \quad (37)$$

where

$$\begin{aligned} H_1(z) &= \frac{1}{M-3} \frac{1-z^{-(M-3)}}{1-z^{-1}}; \\ H_2(z) &= \frac{1}{M} \frac{1-z^{-M}}{1-z^{-1}}; \\ H_3(z) &= \frac{1}{M+3} \frac{1-z^{-(M+3)}}{1-z^{-1}}; \\ H_4(z) &= \frac{1}{M-2} \frac{1-z^{-(M-2)}}{1-z^{-1}}; \\ H_5(z) &= \frac{1}{M-1} \frac{1-z^{-(M-1)}}{1-z^{-1}}; \\ H_6(z) &= \frac{1}{M+1} \frac{1-z^{-(M+1)}}{1-z^{-1}}; \\ H_7(z) &= \frac{1}{M+2} \frac{1-z^{-(M+2)}}{1-z^{-1}}. \end{aligned} \quad (38)$$

As an example, for $M=6$ and $L=1$, the equivalent comb filter has an order of $K=10$. Figure 10 compares the magnitude response of the filter (37) and the equivalent comb filter. Note that this method is not dedicated to improving alias rejection in the comb folding bands but to improving the alias rejection in overall comb stop band, providing in this example a minimum attenuation of about 120 dB.

Similar proposals but with different comb filter decimation factors and orders are proposed

Figure 10. Magnitude responses of equivalent comb filter and method in (Stosic, Milic & Pavlovic, 2015)

in (Stosic & Pavlovic, 2014a), (Stosic & Pavlovic, 2014b), (Milic & Pavlovic, 2014), (Stosic & Pavlovic, 2016).

SOLUTIONS AND RECOMMENDATIONS

The review of the proposed methods for the improvement of comb alias rejection shows that there is a trade-off between the quality of improvement and the filter complexity. In comparison with the original comb zero rotation method, the advantages of the methods in which the rotation term is in a non-recursive form, thus avoiding the possible loss of pole-zero cancellations on the unit circle which leads to instability. Similarly, the methods based on cosine filters and Chebyshev polynomials have advantage of non recursive form. Additionally, the advantage of Chebyshev polynomial method is the

controlled and equal attenuations in all folding bands. The methods based on a cascade of different comb filters provide high attenuation in all stop bands at the cost of the increased complexity.

FUTURE RESEARCH DIRECTIONS

The future applications of decimation systems, especially in communications and in A/D converters impose high demands on the design of decimation filters with high alias rejections and low complexity. Therefore the future trends will be in developing new methods for improving comb alias rejections with the aim to increase the comb alias rejection as much as possible and to decrease the corresponding filter complexity as much as possible. The methods could be based either on comb zero rotation or on new mathematical developments and new structures.

CONCLUSION

In this paper we treated the problem of increasing the comb alias rejection, since the comb filter itself does not provide enough rejection of aliasing. The original comb-zero rotation method rotates the zeros of the comb filter around their original positions, thus introducing two new zeros in each folding band. The inserted zeros increase the widths of the folding bands and increase the attenuation across the folding bands. However, the disadvantage of the method is the introduction of two multipliers, one working at high input rate. Additionally, the rotated filter has poles on the unit circle which are perfectly canceled with the zeros, as far as the infinite precision of the filter coefficients is concerned. However, in the case of finite precision, this cancellation can be lost leading to instability. Different methods have been developed to address one or more issues associated with the original zero-rotation method with the rotation term either in recursive or non recursive forms. The methods with the rotation term in a non recursive form do not have the instability problem. The methods based on cosine filters, Chebyshev polynomials, and the cascaded comb filters have the advantage of non recursive form. Future work can be dedicated to a multiplierless design of filters for the improvement of comb alias rejection with a decreased number of adders, and improved alias rejection in all folding bands.

KEY TERMS AND DEFINITIONS

Aliasing: Unwanted replicas of the main spectrum of the decimated signal.

Comb Filter: Filter with all coefficients equal to unity.

Cosine Filter: Special case of comb filter for $M=2$. It has magnitude response in the cosine form.

Digital Filter: A filter that performs mathematical operations on a discrete-time signal.

Expanded Filter By N: The filter obtained by replacing each delay in the original filter by N delays.

Filter: The system which has function to reduce or enhance certain aspects of input signal,

as for example to remove unwanted parts of the signal, such as random noise, or to extract useful parts of the signal, such as the components with a certain frequencies.

Non-Recursive Form: The transfer function has only the nominator.

Recursive Form: The transfer function has the nominator and the denominator.

Rotated Comb: Comb filter in which all zeros are rotated around the original comb zero positions.

RS Filter: The cascade of rotated comb and comb filter.

A Paradoxical World and the Role of Technology in Thana–Capitalism

Maximiliano Emanuel Korstanje
University of Palermo, Argentina

INTRODUCTION

We live in digital times, where events are covered and disseminated by the media in seconds to a much wider audience (Warschauer & Matuchniak, 2010). Technology not only altered our current means of production, but also the ways life is lived as well as our habits, behaviours and social interaction with others (Gold 2012). The seminal texts of Jacques Ellul about a “technological society” shed light on the negative effects of autocracy imposed by the expansion of technological breakthroughs. The legitimacy of elite is enhanced at the time workforce accepts the cultural value of efficacy as the best of possible worlds. One day, humankind will be strictly controlled by Machines which will be characterized by rationality, artificiality and automatism. Ellul acknowledged that technology was conducive to the culture of capitalism posing instrumentality as mediator between citizens and institutions (Ellul, 1964). Scholars and thinkers are divided respecting to the role played by digital technology in the liberal world of consumers. Not too far from the legacy of Max Weber, Ellul was pioneer in adamantly alerting to what extent technology promotes an atmosphere of further alienation for human beings. However, others voices as Guy Sorman (2008) claims that the forces of progress activate conservative counter-reactions that are oriented to prevent a more egalitarian society. Detractors of technology and its progress only are limited to tell part of the truth, which means the aftermaths of new techniques in the fields of economy but ignoring those achievements promoted by technology as the expansion of life expectative

or the improvements in healthcare overt recent years. As Korstanje and Skoll put it, neither good nor bad technology depends on the use people did. Concerned by the paradoxes of Chernobyl, modernity showed that technology enrooted in a world of complexities and uncertainty would be as “a run-away train” very hard to control. The paradox was that the same instrument will make of our life a safer place to dwell become in a global threat that very well jeopardizes our existence in this planet (Korstanje & Skoll 2014). Here some questions arise: what is the role of Technology in our modern World, is technology a mechanism of control or censorship in democratic societies?, in what way?

Although technology introduced a plenty of liberties and rights for humankind, which are protected by democracy, it resulted in a much deeper disciplinary mechanism that leads to censorship. To put this in other terms, in Medieval Times, writers, thinkers whose text defied the authority of King or Catholic Church were jailed, tortured and condemned to the stake. The power of coercion emanating from Prince exerted violence as an efficient instrument of dissuasion, circumscribing the Leviathan’s whims. The dissemination of books was limited to those authors who were conducive to status quo. In this respect, the power was endorsed by the capacity of prince to create terror in others. Rather, in postmodern times, censorship is preferably achieved by over-production without limits and no matter whom or under what theme the writer focuses on. For example, once we key in Google the name Karl Marx or Max Weber we will get thousands of records of different studies containing or citing both scholars. Since

DOI: 10.4018/978-1-5225-2255-3.ch413

our limited mind can only be read part of these records (not all), we only are restricted to have a partial viewpoint of the problem. In the world of consumption, where liberty plays a crucial role in order for consumers to channel their desire in many directions, knowledge is over-produced to cause misunderstanding in readers. The larger the bibliography consulted, less the derived understanding. For those readers who are not specialized in sociology it is almost impossible to understand modernity only accessing to ten or twenty works bought in bookstore. This happens simply because the censorship in postmodern times is based on the liberty administered by technology to produce without order in many directions. Conducive to mass-consumption, freedom and democracy delineate the contours of societal order making the produced commodities affordable to consumers, but in so doing opens the doors for an atmosphere of conflict and discontent as never before.

Though this point will be explained in detail in the following sections, let's explain the term Thana Capitalism is used to denote a new stage of capitalist system. In this emergent facet not only technology played a vital role subordinating social practice to gazing but also paved the ways for the needs of captivating the suffering of others. In times of Thana-capitalism, risk sets the pace to death as a mediator between citizens and their institutions. We mean to Thana, as a derived term from Thanatos (Greek) from Death. In the days of Thana Capitalism, global audiences gaze spectacles which are based on news, content of disasters, mass-death or trauma. Citizens who are prone to gaze others' death enthrall their own status as a part of privileged-class.

BACKGROUND

Over decades, common questions asked on the evolution of science in Occident. Three different schools explored the interconnection of technology in the maturation of science. Econometrics, which initiate the first family of studies, signalled

to mathematical algorithms to produce top-down knowledge. Everything which cannot be visually tested was systematically rejected as a source of genuine knowledge. Human habits not number were the key factors that distinguished these emerging disciplines from economy. If classic science was prone with the premise of objectivity between *observer and observed*, sociology and anthropology gradually instilled a hermeneutics dialectics of knowledge which based on individual experience gave innovative outcomes (Cuevas 2005). Though this premise was already-evinced by young Marx, since the means of production mould the ideology for the society to understand environment, it is tempting to confirm that technologies are subsumed under an historical dialectic imposed externally by elite. This suggests that things are used to accomplish broader goals, but the underlying meaning for what we use these different objects is externally and culturally imposed by a privilege class (Marx, 1975; 1967; Marx & Engels, 1983). This raises a more than interesting question, is technology a platform to alienation?

For H. Marcuse, the alienatory nature of technology rested on its capacity to alter the cultural background of society, which legitimized the asymmetries of classes (Marcuse 1991). Capitalism has imposed an "economy of desire" which absorbs the wages of work-force (Korstanje 2015). In this respect, David Harvey (1989) argues that modern means of production blurred the different of space and time, accelerating the gift-exchange process. The oil embargo after 1972 produced a serious crisis to West which decentralized the economic system to the extent, that the concept of reality as it was envisaged by Enlightenment set the pace to multi-layered view of reality (Harvey 1989). In this context, French philosophy pivoted a radical criticism against the role played by technology and science in this every-increasing process. From Weber and Sombart's days, there was no other critical thinker as Jean Baudrillard that attacked the epistemological core of capitalism. For Baudrillard, capitalism has successfully expanded in view of the alternations of the

epistemological viewpoint in what reality means. The visual technology in these times has not only altered the perceptions of citizens accelerating the intersection of time and space, but the proliferation of textuality. In sharp contrast to other ages, modernity is based on the rise of computers where the meaning of publicity associates to the electronic World. To understand this better, he cites the example of Precogs, in *Minority Report* film, anticipate to crime before it is committed. This reminds that the visual appearance of events does not imply they are happening in present; as these crimes were forecasted by Precogs in a future that modified the present of potential criminal, now pseudo-events are virtually shaping our sensual realm (Baudrillard, 1986; 1995; 2001, 2002). As Virilio puts it, technology played a leading role not only blurring the borders between past and time, but effacing the difference between reality and pseudo-reality. In consonance with Baudrillard, Virilio understands that modern science remains subordinated to the interests of market, instead of searching in the true, to solve the problems of citizens. More interested in supporting the financial mega corporations, science embraces the paradigms of simulation, which reflects complex algorithms to understand the future. One of the chief aims of science, adjoined to technology, is to prevent the risks that may place capitalist system in jeopardy (Virilio 2010).

Virilio's account is oriented to exploring the limitations of modern science which today are not concerned in understanding issues, but forecasting hazardous events in order for the current system of consumption not to be affected. Doubtless, it opens the doors for a more creative discussion to understand to what extent science and the society of risk are inextricably interlinked.

KNOWLEDGE IN THE SOCIETY OF RISK

The idea of a society of risk was coined by German Sociologist Ulrich Beck in observance of the role

of nuclear technology in Chernobyl, Ukraine. This sudden disaster not only shocked public opinion worldwide, but also evinced the vices and limitations of experts in the manner technology are manipulated. Those instruments which originally would be featured for the benefits of humankind now result in global risks that put society upside down. In this vein, Beck adheres to the thesis that the presence of risk makes societies more egalitarian since all classes are united by the same problems. Paradoxically, this accident created a radical shift in how knowledge is produced and disseminated to lay-people. With the advent of the society of risks, consumption replaced ethics in the line with the fact that hope for full employment sets the pace to insecurity and fear. While lay-people advanced in their knowledge of the world, risks appealed to a process of "reflexibility" where top-down authority of experts was placed under the scrutiny (Beck, 2002; 2009; 2015).

Following this ground-breaking contribution, Anthony Giddens goes on the open points unexplored in Beck's account. For Giddens, capitalism and industrialism are different projects which originally worked dissociated each other. Taking his cue from the "attachment theory", Giddens understands that social ties are represented in the ontological security developed by individuals from their childhoods. At the time, the emerging force of tradition is eroded by post-modernity; the ontological security of citizens will be seriously damaged. Trust serves as a "protective cocoon" in order for people to face the daily threats produced by the system. Without the blessing of trust, lay-citizens are more frightening of future and will look shelter in technology. The process of reflexivity engendered more horizontal circuits of authority, and of course, the system of experts is confronted to the knowledge accessed by lay-people. To wit, the legitimacy of experts in the fields of medicine, to set an example, will depend on the credibility the professional instill in patients. In this stage, trust plays a crucial role configuring the social basis of a society that enthralled global risks as the mediators between citizens and their institutions

(Giddens & Pierson, 1998; Giddens 1991, 1999). In consonance with Virilio, Giddens advises that in a near future, knowledge will be regularized by means of reflexivity in a way that will lead science to be prone to discover elements that help forecasting risks instead of studying facts. At a first look, what would be more than interesting to discuss is to what extent, in post-capitalist societies, the use of digital-technology produces a more efficient censorship.

In regards to the dichotomy of Surveillance and censorship, a must-read book is *Liquid Surveillance*, authored by D. Lyon & Z Bauman (2013). Both agree though 9/11 has not created the current state of hyper-surveillance in modern capitalist societies, no less true is that this traumatic event accelerated its condition of reproduction. The already existent technologies are posed not only to make for public spaces, or households a safer place, but also to remind the importance of those persons who can pay for private security or closed-circuits of satellite control. This book suggests two significant ideas. First and foremost, the state is unable to protect their citizens because the power was conferred to trade. Modern nation state is obliged to give solutions for problems created elsewhere. This engendered a sense of anomie, by which the citizens feel vulnerable. Secondly, the introduction of surveillance technology makes an unsafe world. The quest of order that characterizes the human existence is determined by the needs of change. The paradox lies in everything what we do, is to create a sense of stability we never will reach before death. If the society of risk imagined by Beck considered the risk as a result of action, the liquid surveillance goes in another direction.

As this argument given, Rebecca Fiske reviews the intersection of the state of exception with law-making process, a strand ignited by Schmitt and recently continued by Agamben. Fiske starts from the premise that any law derives from the authority of Gods, and remain affordable for humans in case of emergency. The paradox with this doctrine is that while the notion of exemption supposes breaking the law, sovereign serves as a

symbolic gatekeeper. While this applies very well for tribal societies, in industrial organizations where divinity exerts a moderate influence, the sense of exemption prevails. Fiske acknowledges that after 9/11 US committed some human right violations, in the name of security and well-being. While emergencies allow the delegation of further powers to executive branch, the judiciary often does not express any worry. This pattern would be very dangerous for democracy because it leads to dictatorship. After 9/11 the society of risk passed to a new stage where the spectacle of disasters would be the mainstream cultural value. Risk society mutated to Thana Capitalism, in the same way, the sense of protection set the pace to the needs of gazing others' death (Korstanje 2016). This will be fleshed out in next lines.

THE RISE OF THANA CAPITALISM

In one point, not only Giddens but also Beck took the wrong side of the road. There is nothing as the end of class-society in postmodernity. Neither classes have disappeared, nor are citizens living in a more egalitarian society. In the society of risk, some groups make the decisions that generate those risks other more vulnerable groups will face. Given this condition, those classes which monopolize the financial resources to mitigate risks are situated at the top of society, while lower classes are condemned to experience the catastrophes triggered by decisions that are made in external circles. Lower-classes are far from controlling risks in a Thana-Capitalism, they are subject to witness their effects alone.

Throughout Medieval Times, the access to knowledge was restricted to few hands. Without the print invented by Johannes Gutenberg's, the gathered information was monopolized by Catholic Church and scholars. Those agents, who defied status quo, were coactively repressed and condemned to death. This was an oft-used tactic of censorship that instilled panic in population. Violence and death were everywhere and a peas-

ant has an expectative of life of almost 30 years. However, the invention of print changed everything, enhancing the accessibility to books. The sense of control exerted by the Prince changed to subtler forms which were based on alienation and standardization. As Marshal McLuhan puts it, printing press accelerated a real revolution in European thinking to the extent to produce a mega system of global communication (Global Village) where the efficacy of the system was given by its ability to gather information. However, in this universe, technologies are not inventions only, which very well are affordable to users, but means to produce “identities” that form the character of peoples. High-tech enrooted in the culture to produce habits in users. In one direction, the creation of movable types was a turning point to reproduce thousands of books, which led towards a society of information, whereas unfortunately it was created a “tyranny of visual culture” cemented a *standardized-culture* (McLuhan, 2011).

In our current days, the society of risks examined by Giddens and Beck has gone forever, or at least it has mutated into a new form, *Thana-Capitalism*. Risk-Capitalism essentially was associated to bio politics and the needs of life, Thana Capitalism centres on the opposite, death. In sharp contrast to Medieval Age, in *Thana-Capitalism* people have a high expectancy of life, but live frightened by the possibility of death. Consumers are fascinated to witness spectacles where others are affected, killed or tortured. Death has become in the main cultural value in this new society, where 24 hours per day, TV and Journalism only transmit news linked to death. News that oscillates between disasters, terrorist attacks or local crimes daily captivate an audience more interested to feel more special than consternated for a run-a-way World. In many newscasts, it appears a message that say “images may hurt your sensibility”, or Warning, videos and images not for children”. At a closer look, even if audience in the developed societies are bombarded to catastrophic news with the end of keeping the society in an on-going

state of emergency, no less true is that death was become in a form of entertainment.

Following this argument, Phillipe Aries observed how in modern times though the expectances of life have notably extended; the symbolism of death has been more savage and disrupting for social order. We are now accustomed to live more years than our ancestors and it seems as though we have advanced in our efforts to discipline death, but now we are more afraid about the security of our loved relatives (Aries, 1975). To wit, five indicators are of paramount importance to observe the end of the Risk-Capitalism and the rise of *Thana-capitalism*.

We mean OMG as object Management Group. Further, Table 1 shows differences between Risk and Thana-Capitalism. The society drawn by Giddens and Beck corresponds with Risk-Capitalism. The organization of this system was centred on a decentralized mean of production where globalization attracted heavy investment in any part of the world. The maximization of profits and the reduction of costs was the main goal of risk-society. Even under-developed countries were more attractive for investors because the lower work-force costs respecting to central economies. As Taylor Gooby (2004) noted, the same technology that expanded the expectancy of life and enhanced the quality of life of elderly class produced a serious imbal-

Table 1. Differences of Risk and Thana-Capitalism

	Risk-Capitalism	Thana-Capitalism
Politics	Decentralized	Chaotic
Economy	Segments	Total Competence
Production	Consumption	Survival of the fittest
Main Value	Risk	Death
Event	Oil Embargo (1972)	11 September of 2001
Reaction	Risk Management	Victimization
Pressure Group	OMG	Victims
Censorship.	Fear	Over-production of information.

ance in the social security costs, because active workforce should absorb an ever growing demand of retirees that threatened the balance of the system. Secondly, the adoption of new technology to efficiently maximize profits of capital-owners reduced the supply of jobs for a precaritized blue-collar class. All these events conjoined to the oil Embargo caused by the Arab Israeli war, produced a serious glitch in the well fare state that initiated a new version of capitalism, more based on fear as a dissuasive element of control. In governing through Crime, Simon evinced how Elite appealed to fear in order for workforce to accept economic policies otherwise would be widely rejected (Simon 2007). Neoliberalism alluded to the sensationalism and fear disasters wake up in society in order to ensure a logic of exploitation over workforce (Klein 2007). Since the main cultural value in the society is risk, the reaction of citizens corresponds with the management of risk, which is associated to the needs of protection. As this backdrop, citizens go to private market in the absence of nation-state, where by the paying of a quota of capital they get a temporal sense of security. By means the buying insurances for protection the society of risk still produces new commodities to be exchanged in a global market. The tactic of discipline or censorship over citizens depends on the degree of fear elite can produce in society. Frightened by the presence of global fears that can end with the life as we know, citizens are sensitive to the market to pay for the security the state does not grant. However, one thing is using technology to predict disasters, and other go to the high-tech to produce a “theatralization of disasters”. In the second case, death is enthralled as an attractive factor of western culture in the contemporary World.

During the risk society, people lived afraid the disaster will be next to take place. The specialized literature suggests that risks are not disasters. Risk is a potential danger which can be occur or not. Therefore, the society of risk was oriented to a future. Understanding the dangers hidden in the future will be an efficient attempt to protect the

society. Thana-capitalism, rather, promotes disasters in order to entertain a global audience dubbed as “death-seekers”. Seeing how others die serves as a symbolic platform for watcher to feel how outstanding he or she is. This is the reason why, terrorism or news related to terrorist attacks are covered instantly by the media. We are fascinated by the state of disaster produced by risk society. Technology not only has disciplined the real external or internal threats but it has commoditized lower classes’ suffering as a new type of cultural entertainment (Korstanje 2016).

Doubtless, 9/11 was a founding event for the rise of Thana Capitalism. From this moment on, not only Western audience acknowledged that the world was an unsafe place to be, but they witnessed how their high-tech and transport applications can be used as weapons to the cultural core of the world. In this new era, coaction and violence were futile and censorship was politically manipulated to cause misunderstanding in lay-people. The term Thana-Capitalism stems from the word *Thanaptosis* which was originally coined by poet William C Bryant to symbolize the cycle of life and death. We live in order for others die, and we will die so that others can live. Furthermore, *Thanatos* (Θάνατος) comes the name given to a demon who represented the personification of “death”. In this new stage capitalism signalled to a much complex system of production which exploited the symbolism of death. Since the conditions of production passed from a decentralized model to a chaotic one, where all agents enter in competence with others for surviving, the doctrine of Thana-capitalism follows doctrines of social Darwinism where protection set the pace to *the Survival of the strongest*. Sometimes, holiday-making and vacations give some hints on how societies are changing. Our parents went to beaches or relaxing sites to spend their days while now tourists are exciting to visit spaces of disaster as Chernobyl, Katrina in New Orleans or even the ground zero in New York. Sociologically, if holidays-makers have developed an apollonian sense of beautiness, now they are in quest of spaces of mass-death and suf-

fering to revitalize the psychological frustrations they daily experience in their respective societies. Death has gained traction in thana-capitalism, captivating the admiration and becoming in a real tourist-attraction for many international segments (Bloom 2000; Stone & Sharpley 2008; White & Frew 2013). Knowing further on what purposes people travel exhibits a valid way of understanding on what values society is organized (Korstanje 2015). Is dark tourism a sign of egoism or a real attempt of understanding Death?

Several decades back, George H Mead, one of the fathers of symbolic interactionism, questioned why paradoxically many people are prone to read or listen of bad news presented by journalism, at the time they show preference by these types of news. What is our fascination for other's suffering? He assertively concludes that the self is configured by its interaction with others. This social dialectic alludes to anticipation and interpretation as two pillars of communication-process. The self feels happiness by other's suffering, because it represents a rite necessary to avoid or think in own pain. Starting from the premise the self is morally obliged to assist the other to reinforce its sentiment of superiority, Mead adds, this is the ethical nature of social relationship (Mead, 2009). The same remarks may apply for *thana-capitalism*.

Undoubtedly, the myth of Noah is one of the stories of the Bible that modern cinema has commoditized. This myth not only explains but also legitimize the material asymmetries produced by Thana-Capitalism. Let's remind readers that this God annoyed by the corruption of human beings, mandated to Noah to construct an ark. His divine mission consisted in gathering a pair by specie to achieve the preservation of natural life. The world destroyed by a great flood will be reconstructed by the specie protected by Noah. At a first glance, as the myth was ethically formulated, a formal message is based on the importance of nature and the problem of sin, corruption. But unconsciously, it poses the dilemma of competition where Thana-capitalism is centered. At any tournament or game, there can be only one winner.

Not only the creation but also Noah is witness of other's death, other's mass-death. The curiosity and fascination for death comes from this founding myth. The fact is that it can be found in Reality shows as big brother, a game widely studied by sociologists and detractors of visual technology rests on this principle. The main message of this game is only one participant is the chosen one to win. The doctrine of a selective-oriented salvation, enrooted in Protestantism claims for (though from different angles) understanding death as a token of vulnerability, lack of purity. The question whether people are happier when disaster takes place in other neighborhoods, it is still unclear the intersection of disasters and social bondage (Korstanje 2015; 2016).

It is important not to lose the sight that shrines reminding spaces of disasters are dispositiffs politically enrooted in the "spectacle of disaster", a term coined by Jean Baudrillard. Thematizing on disasters helps to the process of recovery of society in post disaster context, not only because society understands the lesson given by nature, but also poses as valid effort to discipline death. As disasters, death comes at any moment of life. This engenders much anxiety in survivors. In post-disasters environs, survivors develop a much deeper process of mourning to orchestrate the resiliency. They elaborate special rites to overcome the traumatic event that inflicted an extreme sentiment of pain. Any victim, before the climate of destruction, realizes that Gods were benevolent after all. Survivors, that way, embrace a climate of superiority by their subsistence was given by outstanding characteristics such as bravery, moral virtue and strength. This type of reaction helps community to recover to adversity but may generate sentiments of nationalism, superiority or ethnocentrism if it is not limited. The superiority of survivors, in this vein, depends on the other's misfortune. Unless this sentiment of narcissism to be regulated, it produces a clear rupture that affects social solidarity. Survivors feel they are super-heroes or special people touched by Gods, their mandates not only are sacred but also just. In

this moment, this sentiment of superiority feeds back a much deeper stage of victimization where survivors feel that pain is the only mean to reach happiness. Quite aside from this, their losses make them special for others who have not faced the same situation. This is exactly the instance where trust is undermined in order for the loyalty of citizens to be subject to market-place. Whatever the case may be, Thana-capitalism in sync with existent visual technology, not only exploits these types of climates but also obscures the causality of events. French ethnologist, Marc Augé acknowledged that the mass-media portrays tragic events blurring the connection between causes and consequences. News or stories focus on the effects instead on a clear diagnosis of reasons behind. As a result of this disasters' are continuously repeated once and once again (Augé, 2002). Not surprisingly, mass-media disseminates on a daily basis, news containing stories of victims to reinforce the above described sentiment of Narcissism.

CONCLUSION

In Thana-capitalism death is the main commodity which is produced and disseminated by the media worldwide. As in dark tourism practices, people are interested to gaze the Other's suffering but in fact far from being closer to others, it reinforces their happiness not to be touched by death. Since thana-capitalism is based on a social Darwinism where all are struggling against all to survive, others' death endorses an exclusive sign of supremacy for those who are still alive. Metaphorically speaking, in thana-capitalism life is understood as a thrilling trace where only few selected participants reach the glory. As in reality-shows as Big Brother, or Films of Hunger Games, Thana Capitalism stimulates the competence of all against all. Ideologically, narcissism allows the participation of innocent people in this cynic game. This suggests that participants of these games not only are unfamiliar with their real probabilities to fail, in view the fact that they are moved by their

own egocentrism. That way, Status quo which promotes the logic of divide and rule undermines any efforts of other groups to take the power. In these scenarios, never participants are sufficient stronger to break the arbitrariness as well as the law of elite. Of course, because this law cannot be broken, is the reason why Thana Capitalism reproduces serious material asymmetries in society where few citizens gain almost all, once the rest is pressed to live in the ruins. Without social Darwinism, Thana Capitalism, which should be framed into a new stage of capitalism, would never exist. In this system censorship is not exerted by coercion, which is symbolically rechannelled by the figure of death, but by over-production of scattered information. Articulated in a more efficient way, now modern users have access to a lot of information but at the same time their understanding is in decline.

As discussed throughout this chapter, at time of researching for some issues the records visible in the media prevent a coherent understanding of social issues, this multiplication of information paved the ways for a paradoxical situation where only few hands monopolize what can be or not written. If in medieval times, the censorship was oriented to violence now it is related to liberty and the scattered information that leads to misinformation. This is only possible in a new era, dubbed as "Thana-Capitalism". Nowadays, technology offers a fertile ground to visualize the suffering of "Others" connecting our self to death, but at the same time stimulating the over-production of information (which oscillates between books, magazines, papers to visual material) that keeps lay-people aside from the understanding of events. With the benefits of hindsight, we confirm that death, censorship and technology are inextricably intertwined. In medieval times where death was a very common thing in day-to-day life, produced-information was reduced to limited circles. The lower technical condition of production was prone to use violence to exercise censorship to unauthorized voices. People frightened death in the same extent than god. However, in secularized

Thana-capitalism people reject the possibility of a “heaven”, or eternal shelter. There is nothing beyond death which sounds interesting for consumers of Thana-capitalism. The main value of this society is not life, but death. Once death has been liberated from her cage, society neglected God adopting technology as a valid vehicle to expand life. The belief in heaven as an exemplary centre where only chosen souls enters have been replaced by an atmosphere of eternal competence here in hearth, where participants struggle to gain recognition. This technology is not restricted; it has been democratized to be used by wider audiences worldwide. However, this resulted in an unexpected consequence. The unlimited overproduction of digital information produced a subtle censorship by the decline of understanding. By abundance, the produced knowledge is scattered in thousand pieces almost impossible to gather into a puzzle. Last but not least, thana-capitalism foments an eternal atmosphere of competence only if real violence is reduced to zero or to the minimum desirable degree. If this thesis is correct, what is the position of violence in this model?.

LINES FOR FUTURE RESEARCH

The argument held here may find much criticism in liberal thinkers, who argues that capitalism helped not only to crystalize democracy but making of this world a less violent realm (Pinker, 2011). However, the problem of capitalism rests on the belief that few deserve much, while the rest are on the ruin. Almost 2% of global population concentrates 90% of produced wealth. In a recent book, Maximiliano Korstanje (2015) alarmed that this postmodern world can be compared to the film *Hunger Games*, or the reality show *Big Brother*. In both settings, participants are dominant of their conciseness because they remain unfamiliar with the real probabilities to fail. These competences, like liberal market, are based on the premise of social Darwinism that claims for “the survival of strongest”, which means that the glory of only one

equals to the failure of the whole rest. Participants not only over-value their own skills, but are confident of their strongholds. The stimulation of competition in the labour market, emulated by entertainment industry, resulted in two interesting dynamics. The vulnerability of rank-and-file workers associated to the decline of well-fare state facilitated the capital-owners to increase their profits and wealth, while risk was adopted as a new value for modern workers. After all, the spectacle of disasters confers to workers the idea they are co-manager of their own fate. As things come from worse to worst, workers not only are responsible by decisions others make, but in Thana-Capitalism, elite eludes its responsibilities to fail in paving the conditions for a fairer wealth distribution.

On another hand, capital flourishes in a climate of liberty to move across the world. The doctrine of liberty (democracy) stimulates in workers the needs of consuming, in terms of Donohue, a type of freedom from “want”. The change from a society of producers to consumers took hit after 40s decade. Ideologically, Americans have felt “superior” to other nations because they are enthralled as the main democratic and prosperous society; although more egalitarian at the surface, American citizens are subject to more work and consumption but less leisure. This happens because, in a pro consumer society, workers are bombarded with emulation and advertising creating the needs to buy. This not only jeopardized their real liberty to choose, but affects seriously to democracy. Detractors of capitalism, who pushed their focus on the arbitrariness of producers, were involuntarily responsible or conducive to the formation of a global society of consumers. Those denunciations on an economy that protect the interests of producers as well as the needs to adopt consumption to break the material asymmetries among classes, were two guiding concepts to the formation of a globalized version of capitalism, which paradoxically was prone to mass-consumption but producing serious vulnerabilities (Donohue 2003). Despite the hot-debate ignited in this chapter, we feel much deeper

investigation is necessary in order to provide an all-encompassing model to understand these times where death seems to be exchangeable in every spheres of society. Precisely, in Thana-Capitalism digital information acts as mechanism of censorship successfully orchestrated by over-abundance.

KEY TERMS AND DEFINITIONS

Digital Surveillance: The use of digital technology to control others, citizens and the life of a nation.

Censorship: It means the suppression of free speech rights or any right to express own ideas.

Risk Society: The ways a society reacts against the rise of risks. Risk society alludes to the needs of forecasting future to prevent potential threats that may affects societal order.

Thana-Capitalism: This represents a new term just coined in this manuscript where death situates as the main commodity of good exchange process and current economic systems. Thana capitalism replaced risk society after 9/11.

Globalization: Refers to a cultural project of integration of economies and networks which leads to multiculturalism and interchange of worldviews.

Performance Measurement of Technology Ventures by Science and Technology Institutions

INTRODUCTION

Developing and transitional economies are keen to advance their science and technology in augmenting social and economic progress so as to catch up with developed economies. While the concept of national innovation system gains significant interest among emerging economies, institutions for science and technological innovation have been established to nurture the growth and expansion of technology ventures (Freeman, 1995). Since the early 1980s, institutions in the USA, UK, Germany, France, and Japan have been established to stimulate their countries' economic development through technological innovation and advancements of their emerging industries. Local universities have been involved as well. For instance, Massachusetts Institute of Technology (MIT) in the U.S. developed its Industrial Liaison Program in 1948 (Liu & Jiang, 2001). In China, the University-Industry Cooperation Committee of Tsinghua University (UICCTU) was established in 1995, providing various collaborative services for the member companies including IBM, Motorola, Hitachi, and NEC (Liu & Jiang, 2001).

In recent decades, an increasing number of science and technology institutions (STIs) have been founded to pursue the development of high technology companies in partnership with enter-

prises with the aim of undertaking joint projects for the assessment of new technology ventures (De Coster & Butler, 2003). The growing importance of technological innovation in national economic development has been increasingly recognized. China, as a transitional economy, has stepped up its Research and Development (R&D) expenditures and advocates institutional collaboration with the private sector for innovation performance (Boeing, Mueller, & Sandner, 2016; Kafourous, Wang, Pipropoulos, & Zhang, 2016). Hong Kong, China's special administrative region, established its Innovation and Technology Bureau in early 2016 as an effort of the government to foster innovation and technology industry in collaboration with local universities and its Science Park.

However, challenges remain significant in performance measurement and management for STIs' effective development, given the intention to reduce the rate of failures among early-stage ventures. Prior studies looked into issues with managing performance of technology ventures (Ganotakis & Love, 2012; Li & Atuahene-Gima, 2001). These studies that focus on specific dynamics of growth and development from the standpoint of resources allocation process did not fully examine pertinent externalities. Externalities, such as market competitions, applications, and commercialization of emerging disruptive technolo-

gies, would further complicate the environment and potential success of new technology ventures.

This chapter explores the dynamics between resources management and external landscapes as critical consideration in performance measurement and management of technology ventures. Based on an interdisciplinary literature review, a pertinent framework is developed with a set of monitoring areas and success indicators. The authors argue that STIs would have to utilize their expertise in specific clusters as intangible resources to assess product development and innovation capabilities as competitive strengths among the ventures. However, there could be limitation to the efficacy of a top-down, mechanical planning and control approach adopted by STIs to facilitate the innovative development of an emerging technology sector, given the constant dynamics of external markets.

BACKGROUND

Technology Monitoring and Assessment by STIs in Emerging Economies

STIs require a systematic corporate approach to monitor and assess the ongoing development of science and technology in order to capture the next big waves. At a country level, the concept of national innovation system is supported by the use of technology foresight techniques to strengthen its effectiveness among developed countries (Martin & Johnston, 1999). The use of a national innovation system is also advocated for the promotion and formation of partnership for effective technology development within a developing country (Hall, Bockett, Taylor, Sivamohan, & Clark, 2001). Bradford, Kinzey, and Gunn (1991) pointed out the importance of having a structured approach to monitor programs in both public and private sectors on a global basis. Their study also proposed a schematic to outline both internal and external aspects, as well as to keep abreast of technological changes in order to ensure a healthy development

of an organization. Nevertheless, expertise is needed to provide in-depth and timely review of the associated technology sectors.

Lichtenthaler (2004) used a case study to outline a framework that demonstrates the need to assess technological change through structural, hybrid, and informal forms for coordinating technology intelligence processes. This framework is made of coordinative forms of technology intelligence at both company and technology levels. The dynamic environments of technology ventures, as investigated by Zahra and Bogner (2000), are highly crucial to the determination of these concerns' internal development and exploitation of technological resources, and therefore to their performance and even survival. Under such a competitive environment, technology ventures are pressured to develop new products, upgrade them, and strengthen R&D in a timely manner, especially under the highly competitive markets of developed economies.

However, STIs could be hindered by their internal bureaucracy and formal constraints while the external environment changes rapidly. As North (1990) noted in his examination of institutional performance,

The major role of institutions in a society is to reduce uncertainty by establishing a stable (but not necessarily efficient) structure to human interaction. But the stability of institutions in no way gainsays the fact that they are changing.... Institutions typically change incrementally rather than in discontinuous fashion. (p. 6)

In light of emergence of disruptive technologies, an institution could have neglected such changing externalities and missed an opportunity to counter swiftly.

Challenges in Nurturing Early-Stage Technology Ventures

The emergence of technology ventures creates positive effects in modern economic development fostering innovations of industries; however,

early-stage technology ventures typically face a number of challenges. One of the main concerns is related to these enterprises' optimal utilization of limited resources during their early development. Chan and Lau (2005) examined the criticalness of resources provided by the incubators to technology start-ups in a science park. In financing the expansion of a venture, evidence shows that agency costs could become significant when there are less tangible assets, more growth options, and lower asset specificity (Gompers, 1995). As a result, venture capitalists will incur increased monitoring costs, especially when R&D intensities are higher (Gompers, 1995).

New technology ventures suffer from a "liability of newness", which can be seen as the root problems and struggle to survive in their early stages (Aspelund, Berg-Utby, & Skjevdal, 2005). Thus, managing internal capabilities in the commercialization process and ensuring resource development effectiveness are crucial in assuring young technology ventures' survival and growth (Burgelman, 2012). Another challenge for new ventures is the conspicuous lack of organizational experience leading to "exacerbating" the cost of internationalization; therefore, a large resource endowment is considered an advantage so as to enhance survival and growth (Sapienza, Autio, George, & Zahra, 2006).

Range of Intellectual Capital as Organizational Resources and Performance Drivers

The resource-based view (RBV) of technology ventures focuses on a bundle of intangible resources which are valuable, scarce, and difficult to imitate, but combined to significantly affect a venture's performance (Lee, Lee, & Pennings, 2001). The theory of RBV considers intangible resources as critical for technology ventures. In order to grow technology ventures, the acquisition of intangible resources, such as human resources and managerial resources, are substantial in es-

tablishing ventures' durable competitive advantages and performance (Brinckmann & Hoegl, 2011). Eisenhardt and Schoonhoven (1990), as well as Brüderl and Preisendörfer (2000), further emphasized the attributes of ventures' top executives, including executives' education and gender, management-specific skills, and level of work experience, would help boost up the success of technological start-ups. In an earlier study, Cooper, Gimeno-Gascon, and Woo (1994) noted that initial human capital and financial resources are key factors to predict a new venture's future performance. As young ventures lack experienced entrepreneurs, financial resources are becoming significant for new ventures. Although financial resources are not based on RBV as they are tradable, non-scare and invaluable, they can be considered as a sustainable competitive advantage for new technology ventures (Lee et al., 2001).

In order to facilitate subsequent growth to another stage, functional specializations as well as heterogeneous resources, composed of tangibles and intangibles, should be available to support the growth of technology ventures (Kazanjian & Drazin, 1990). Lee et al. (2001) revealed that entrepreneurial orientation includes organizational processes, methods, and styles used to implement ventures, whereas technological capabilities are related to patents protected by law, technological knowledge, and production skills.

In reviewing "spin-off" high-technology ventures originated from research performed by a university, De Coster and Bulter (2003) found that these ventures are able to maintain relatively more competitive advantages than the others due to their protected intellectual property. The authors also noted the criticalness of the product innovation level and market potentials. An optimal combination of intangible and tangible resources, considered as intellectual capital, during various stages of development would provide a potential source of competitive advantage for technology ventures in the new economy (Hayton, 2005; Ng, 2006, Ng 2008).

Product Innovation Capabilities

Prior studies indicated that product innovation is a critical driver in measuring technology performance (Li & Atuahene-Gima, 2001). As managerial and financial resources are normally limited for new ventures, product innovation typically involved a certain level of risk (Eisenhardt & Schoonhoven, 1990). In order to succeed, technology ventures must swiftly devise their new products and subsequently innovate them, especially within a market that could be influenced by disruptive technologies (Nambisan, 2002; Schilling & Hill, 1998). Product development itself could be an inherently risky process, in particular when new technology is adopted (Littler, Leverick, & Bruce, 2003). Its production effectiveness and the time to market would further make a new product fragile to competition. The overall product innovation capabilities need to be assessed carefully as part of a venture's performance evaluation.

Dynamic Performance Measurement System for Technology Ventures

Under highly competitive pressures within a technology sector, new ventures with support of limited financial resources struggle to sustain their performances as closely monitored by their equity stakeholders. In particular, venture capitalists are found to be an important group of investors who would use both formal and informal means to monitor the performance of their invested portfolio of ventures while constantly performing strategic analysis of the external competitions (Gorman & Sahlman, 1989). Despite this rather unstructured role, their monitoring style reflects a dynamic characteristic, as a venture's performance needs to be examined in light of the externalities.

Laitinent (2002) further explained the concept of a dynamic performance measurement system which would enable the stakeholders, including the management, to utilize an integrated approach to actively review competitiveness and the internal resource allocation processes. Bititci, Garengo,

Dörfler, and Nudurupati (2012) pointed out the real challenge lies in the development of a dynamic performance measurement system as a social system that enables learning in "autopoietic networks". Bititci et al.'s (2012) study suggests that taking a holistic approach in the development of a dynamic performance measurement system would recognize the concurrent nature of challenges that the stakeholders face in technological contexts.

Alignment of Interests Among the Stakeholders

As a whole, there should be consideration for the alignment of interest among the stakeholders within a performance measurement system in order to facilitate a new venture's goal congruence (Chenhall, 2005). Objectives differ across stakeholders and may have different time horizon; thus, at institutional level, stakeholders need to share a long-term interest and reward system that motivates them to enhance performance. At organizational level, the founding management team's performance needs to be incentivized. In order to avoid myopic behavior, the design of the alignment of interests is particularly crucial for the institutions which are not necessarily motivated by economic interest on an individual basis, but for their institutional objectives. Effective communication should be utilized to accelerate stakeholders' alignment of interests. Indeed, continuous and direct interaction among stakeholders is the basis to establish common institutional objectives (Al-Kwafi & Ahmed, 2013).

Proposed Framework

As Neely, Gregory, and Platts (1995) pointed out, as no single measure can represent all the salient characteristics of an activity, a set of measures is necessarily required for a performance measurement system. Figure 1 shows the framework of a dynamic performance measurement system for technology ventures. It consists of three dimensions, suggesting the dynamic relationship be-

Figure 1. Framework of dynamic performance measurement system for technology ventures

tween a STI and a cluster of technology ventures under its supervision and monitoring. First, STIs need to maintain a timely technology foresight with constant assessments and identification of relevant core technologies. Second, STIs should assess the technological position of ventures in relation to their competitors with respect to new product innovation and commercialization by exploiting new technologies (Geum, Lee, Kang, & Park). Third, STIs have a critical role in the assessment and monitoring of emerging technologies, as well as of external competitors from the market place, in order to make appropriate judgment about their ventures' performance.

In addition to reviewing the composition of intellectual capital within these ventures, the supervising institutions need to proactively review the progress of their product development and innovation in light of the evolving externalities. Institution-related resources, such as the technological infrastructure provided by the institution, quality of its staff, and industrial networks could make a difference in the venture development (González-Pernía, Kuechle, & Peña-Legazkue, 2013). These STIs in turn are required to develop their internal capabilities, including funding, government support, and high quality research staff (Liu & Jiang, 2001). Such capabilities enable researching and analyzing the landscape

of technological innovation within their core technology clusters while anticipating potential disruptive technologies.

Scanning Competitions and Potential Applications of Emerging Disruptive Technologies

It is important for STIs to evaluate potential applications of emerging disruptive technologies so as to assess the relative competitive position regarding potential disruptive technologies of ventures. This can be done by comparing the key disruptive technology's performance of the ventures and of the major competitors on the focal mainstream (Yu & Hang, 2010). An STI may also collect pertinent information and data from the customers, manufacturers, dealers, consultants, and experts. Some may adopt an importance-performance matrix as a tool to evaluate the performance of internal and external services using two measurement dimensions: importance to customer and performance of services (Slack, 1994). Leong and Tan (1992) also developed an importance-performance matrix approach to assess a firm's national competitive superiority, which was measured by two dimensions: importance to investors and country's competitiveness.

In order to evaluate potential applications of emerging disruptive technologies, a technology strength-competitiveness matrix is proposed in Figure 2. Potentials of disruptive technologies can be measured by two dimensions: strength of technological innovation within and competitive technology position. Under strength-competitiveness matrix, the latter's competitive position in the marketplace is evaluated with respect to specific technological innovation in product development, commercialization and resulting market share in comparison with external competitors. The ultimate goal of each technology venture is to achieve the goal of the technology leader and highly competitive technology position (high-lead) of the matrix. Internal strength of technological innovation refers to a venture's ability to develop potentially disruptive technologies on a continuous basis, largely through dedicated R&D activities.

Areas of Monitoring and Success Indicators

A set of structured tools need to be developed in order to monitor the performance of the technology ventures that are engaged in formal

collaboration with STIs and to keep track of these ventures' dynamic performance within a technology cluster. Relevant success indicators in the areas of resources capabilities, emerging disruptive technology, scanning competitions. and performance of new technology ventures are proposed to allow STIs to monitor key aspects of performance (see Table 1).

FUTURE RESEARCH DIRECTIONS

In future studies, the framework proposed in this article will be integrated with specific performance indicators for an evaluation from early-stage to expansion-stage ventures. Alignment of interests between an institution and the ventures being monitored needs to be examined in order to ensure the overall validity of this dynamic performance measurement system. Specific case studies on a science and technology cluster can provide evidence about the relevance of this proposed framework while examining the needs to develop particular performance indicators for the cluster.

Other studies may also explore the influence of a national culture over performance management for technological innovation. In particular, a top-down innovation system under a command economy largely driven by central planning, such as China, should be explored for its differences in institutional performance versus a highly market-based system in the West, which is mostly driven by free flow of information, rationing, and motivation under a competitive market economy. Empirical studies or in-depth case studies under national cultural logics can provide evidence about the relevance of various components of this proposed framework. Comparative studies with Western economies, that have prevailed in intangibles and software developments, would further reveal how emerging technology enterprises from China have grown and developed from its sizable domestic market, with emphases on technological infrastructure and hardware, (e.g., China has identified its high-speed railway technology as

Figure 2. Strength-competitiveness matrix on disruptive technologies

Table 1. Areas of monitoring and success indicators

Areas of Monitoring	Characteristics	Indicators
Resources capabilities	Entrepreneurial orientation, technological capabilities / knowledge assets, and human capital	• Number of high quality R&D employees (Lee et al., 2001). • Range of technologies that were internally developed (Ahuja & Katila, 2001). • Effectiveness of R&D investment (Motohashi, 2005). • Number of patents obtained or submitted (Motohashi, 2005; Perkmann, Neely, & Walsh, 2011). • Overall technological capabilities pertinent to new product design and development (Lee et al., 2001).
Performance of a cluster of technology ventures	Ability to sustain continuous growth and development as a new business venture.	• Exponential growth in employment (Brüderl & Preisendörfer, 2000). • Time to market or product commercialization process (Snow Fjeldstad, Lettl, & Miles, 2011). • Sales volumes (Lee et al., 2001). Sales growth (Lau & Bruton, 2011).
Emerging disruptive technologies	Potential applications of emerging disruptive technologies.	• Count of emerging disruptive technologies (Yu & Hang, 2010). • Commercialization opportunities (Frishammar, Lichtenthaler, & Rundquist, 2012). • Strength of technological innovation (see Fig. 1)
Scanning competitions	External competitions with the global marketplace.	• The level of relative technology competitive position (see Fig. 1)
Venture-institution collaboration/ integrative efforts	Success in collaboration between technology ventures and institution.	• Joint objective setting (Perkmann et al., 2011) • Interaction intensity (Lee et al., 2001) • Effective formal and informal communication (Al-Kwafi & Ahmed, 2013)

part of its national strategy for its infrastructure development with timely commercialization through domestic market penetrations).

CONCLUSION

In this article, a framework that integrates critical knowledge about technology monitoring and assessment of potential disruptive technologies from the standpoint of an STI is proposed on the basis of an interdisciplinary literature review. An effective integration of emerging disruptive technologies into venture strategy is conceived as a critical aspect for the development and growth of technology ventures. An STI is contemplated as a technology assessor that monitors a cluster of ventures continuously pursuing technological innovation to enhance their products. The proposed framework and its dimensions are introduced to help evaluate potential applications of emerging disruptive technologies and assess the relative competitive position of a new venture in harnessing pertinent disruptive technologies within a timeline of commercialization. The areas of monitoring and indicators with time lag potentials are devised to reflect the key dimensions embedded in a dynamic performance measurement system over time.

Further, we suggest there is a dynamic relationship between an STI and a cluster of technology ventures under its supervision and monitoring. An STI has a critical role in monitoring emerging technologies as well as external competitions from the global marketplace in order to make appropriate judgment about the performance of these ventures. Instead of maintaining a top-down, mechanical approach in its strategy formulation and implementation seemingly useful for infrastructural projects, the challenge for an STI in an emerging economy is to assess internal capabilities and more importantly externalities of emerging disruptive technologies over time, being critical to the development and growth of technology ventures striving for product innovation against competitions. Moreover, performance indicators

need to be adapted over time for instituting a culture that supports the dimensions of the proposed performance measurement system.

Nevertheless, the ability of an STI to interact with externalities and to anticipate disruptive technologies remains a challenge. As noted by North (1990), “*Institutions typically change incrementally rather than in discontinuous fashion.*” It is even more so for STIs to embrace changes with timely technology foresights as they have to deal with clusters that are undergoing rapid technological developments and emerging competitive forces on a global basis.

KEY TERMS AND DEFINITIONS

Disruptive Technologies: Emerging technologies that challenge the established players in an existing industry with potential displacement of its range of products and services through technological innovation.

Performance Measurement: The approach in collecting, analyzing and reporting a range of financial and non-financial indicators on past performance of an organization with implications for its future.

Technological Innovation: The process of new product or service development through integration of complementary technologies for adoption by the marketplace.

Technology Ventures: Emerging business entities during their early development and growth with exploitation of technologies and transforming such technologies into new products or services for rapid business growth and development.

Science and Technology Institution: Large established organizations that facilitate the development of science and technology through various research and development (R&D) as well as technological innovation activities.

The Skills of European ICT Specialists

Francesca Sgobbi

University of Brescia, Italy

INTRODUCTION

Specialists in Information and Communication Technologies (ICTs) are professionals “who have the ability to develop, operate and maintain ICT systems” and for whom “ICTs constitute the main part of their job” (OECD, 2004, p.219). ICT specialists play a crucial role in supporting the growth of the information society. However, some signals exist that in mature industrialized economies such as the European Union (EU) the supply of ICT specialists has been falling behind the demand and the evolution of their professional profile may not accompany the growing request for non-technical complementary skills (Eurostat, 2015a; Hüsing *et al.*, 2015).

After a brief survey of the international literature on skill-related issues that may affect the further development of ICT-based applications this article depicts the state-of-the-art of the professional skills supplied by ICT specialists in 11 EU countries based on data from the OECD Survey of Adult Skills.

The first part of the empirical analysis focuses on the skills profile of ICT personnel from EU countries and examines to what extent the higher skills displayed by ICT specialists depend on a different distribution of demographic characteristics and job characteristics compared to the rest of the workforce. The second part of the empirical analysis focuses on the relationship between skills and wages and tests whether employers recognize an occupation-specific wage premium to ICT specialists.

BACKGROUND

Pervasiveness characterizes ICT solutions as general purpose technologies, i.e., technologies whose innovative applications impact everyday household life besides spanning across different business sectors (Jovanovic and Rousseau, 2005). This pervasiveness rose hopes that ICT-based innovations would stimulate cross-industry virtuous circles between investments, innovation, productivity, consumption, and employment able to solve the “jobless growth dilemma” apparent in the USA and the EU in the 1990s (Selhofer, 2000). However, the complementarities between existing and new technologies (Davis and Wright, 1999) and the lack of digital skills among ICT providers and end users soon pointed out risks that skill shortage may obstacle the achievement of expected benefits (Selhofer, 2000).

After twenty years of debate on the occupational effects of ICTs the picture is still unclear. Spiezia *et al.* (2016) suggest that ICTs cause a drop in labor content per unit, hence reducing the demand for labor, but at the same time they raise labor productivity, hence increasing the convenience of labor compared to other productivity factors. Overall effects on labor demand are expected to disappear in the long run, due to a reallocation of labor from traditional sectors to innovative, ICT-intensive ones. Nevertheless, the current framework is still undergoing adjustment processes. Investments in ICTs raised the demand for labor in OECD countries between 1990 and 2007, but reduced it afterwards (Spiezia *et al.*,

2016). In addition, after 2007 the decline in labor demand has been accompanied by polarization between high-skilled and poorly-skilled jobs at the expense of middle-educated workers (Michaels *et al.*, 2014). Job polarization happens because, due to their programmable nature, ICTs tend to substitute labor in case of routine tasks, which prevail among middle-skilled workers. In contrast, knowledge-intensive non-routine tasks concentrate among high-skilled employees whereas labor-intensive non-routine tasks, often concerning the provision of personal services, prevail among low-skilled workers (Autor *et al.*, 2003).

If the diffusion of ICTs has so far deluded the expectations of jobs growth in the whole economy, focus on ICT employment provides a more positive picture. According to Hüsing *et al.* (2015), the ICT professional workforce in Europe in 2014 comprised 7.5 million workers, or 3.5% of the European workforce, with United Kingdom, Germany, France, Italy, Spain, Poland, and the Netherlands accounting for three quarters of total EU ICT professionals. OECD countries present a similar share of ICT specialists (3.6% of workforce in 2014, OECD, 2016).

ICT specialists were not affected by the recent economic crisis. Eurostat (2016) reports a 4% annual growth rate between 2006 and 2014. OECD (2015) reports stable employment levels within the ICT sector in the last decade (2004-2013), which results in growth in the number of ICT specialists, who comprise at least 3% of total employment in most OECD countries, at the expenses of less professionalized roles.

If non-ICT workers are increasingly required to master ICT generic skills besides the core skills of their professional domain, ICT-specialists face the challenge of adding non-technical ICT-complementary skills to their traditional expertise. The emphasis on “soft skills” signals a shift in the nature of ICT specialists’ work and impacts the design of educational curricula (Chillas *et al.*, 2015). Besides facing the challenge of adjusting their curricula European faculties of Computer Science, one of the main sources of ICT special-

ists, have seen a decline in the number of their students and graduates (Hüsing *et al.*, 2015).

The risk of lower inflows from tertiary education, together with some signals of hard-to-fill vacancies, has raised concerns about a possible shortage of ICT specialist skills. However, not all studies agree on this point. OECD (2016) reports stable or even decreasing vacancy rates since 2007 in OECD countries. In addition, 38% of EU enterprises which recruited or tried to recruit ICT specialists in 2014 reported difficulties in filling ICT vacancies (Eurostat, 2015a). However, ICT-specialist recruiters represent only 20% of EU firms. This means that only about 3% of EU enterprises report ICT-related hard-to-fill vacancies and this figure has not changed from 2012 to 2014 (OECD, 2016).

ICT SPECIALISTS IDENTIFICATION AND DATA

A quantitative analysis of the skills provided by European ICT specialists requires a clear identification of these professionals, usually based on either the industry they work in or their occupation. Given the pervasiveness of ICT jobs across industries and enterprise functions (Eurostat, 2015a; Hüsing *et al.*, 2015) an occupation-based approach seems more appropriate to identify ICT specialists and characterize their skills. Eurostat (2015b) details a list of occupations used to operationalize a statistical definition of ICT specialists. Relevant occupations are identified based on the 4-digit level of the 2008 release of the International Standard Classification of Occupations (ISCO-08).

This article resorts to the Eurostat criterion to identify EU ICT specialists based on the OECD Survey of Adult Skills (Figure 1). This survey was developed within the wider OECD Programme for the International Assessment of Adult Competencies (PIAAC Survey). The PIAAC Survey, run between August 2011 and March 2012, inquires

a representative sample of individuals aged 16-65 in 22 OECD countries (OECD, 2013).

The PIAAC Survey provides suitable data to analyze the skill profile of European ICT specialists, since information on education and learning is complemented by a large set of questions concerning experience in the labor market, working conditions, and personal and household background. The dataset also includes the outcomes of field tests for the assessment of individual proficiency in literacy, numeracy, and, for some countries, problem solving in a technology-rich environment. Unfortunately the Eurostat approach to identify ICT specialists requires information on 4-digit ISCO-08 occupations, which not all EU countries collect. For this reason the empirical analysis is restricted to 11 EU countries (Belgium, Czech Republic, Denmark, France, Germany, Italy, Netherlands, Poland, Slovakia, Spain, and United Kingdom). Nevertheless the selected sample accounts for 80.1% of EU population and for 85.5% of EU gross domestic product in 2014.

The distribution of ICT specialists in the examined EU countries as a percentage of total employment resulting from PIAAC data is quite similar to that reported by Eurostat (2016). In almost all countries the share of ICT specialists is above 3% of total employment, which corresponds to an estimate of over 5.3 million ICT specialists.

DO EUROPEAN ICT SPECIALISTS PROVIDE BETTER SKILLS?

Table 1 compares individual and demographic characteristics of ICT specialists and other workers in the examined countries, whereas Table 2 reports information on job characteristics. Both tables outline that ICT specialists comprise a very peculiar subgroup of the total workforce.

In line with the data reported by Eurostat (2016), males largely prevail among ICT specialists, who are on average younger than the rest of the workforce. Average educational qualifications of ICT specialists are always higher than those

achieved by other employees. ICT specialists differ from the remaining working population also in terms of personal background. On average, the parents of ICT specialists achieved higher qualification levels in all the examined countries. In addition, with the only exception of France the share of native speaking population is always higher among ICT specialists.

Three columns in Table 1 report the outcomes of the PIAAC Survey field tests of interviewees' literacy, numeracy, and (for a subset of countries) problem-solving along a 0-500 scale. Despite large cross-country variance, the scores achieved by ICT specialists in cognitive skills tests are always significantly higher compared to the rest of the workforce, especially in the case of numeracy skills. The last column in Table 1 reports a measure of non-technical skills surveyed by PIAAC (Soft skills). The normal variable Soft skills is calculated by means of a factor analysis on 12 variables that assess how often, in a 1-5 scale, individuals are asked to provide leadership, communication, or relational skills. As in the case of cognitive skills, ICT specialists declare more frequent provision of soft skills than other workers.

Table 2 shows that the demographic and individual favorable conditions enjoyed by ICT specialists correspond to better employment conditions. ICT professionals concentrate among skilled occupations. The more dynamic nature of the labor market for ICT specialists also in a period of economic crisis is confirmed by the higher number of jobs held in the five years before the PIAAC Survey. The share of ICT specialists and non-ICT specialists with a temporary contract is similar only for Belgium and Italy. In all other countries ICT specialists enjoy a significantly higher employment security, especially in the Czech Republic and the United Kingdom. The last column in Table 2 shows that also the frequency of part-timing is much lower among ICT specialists compared to other workers.

Data in Tables 1 and 2 confirm that ICT specialists significantly differ from the rest of the working population of the examined EU countries

Figure 1. EU ICT specialists by occupation

Source: Elaboration on PIAAC data

in terms of both individual and job characteristics. The higher proficiency in cognitive skills (literacy, numeracy, and problem solving) and the more intense provision of soft skills assessed by the PIAAC Survey in the case of ICT specialists may consequently follow from the concentration of favorable characteristics among ICT specialists—a

higher educational qualification, a more favorable family background, an occupation that provides more learning opportunities—rather than depending on these professionals’ core capabilities.

To assess whether ICT specialists provide higher cognitive skills after taking into account the impact of other employee-specific, job-spe-

cific, or country-specific features Table 3 reports the results of an Ordinary Least Square (OLS) regression where the dependent variable is the numeracy score achieved in the PIAAC Survey. Focus on numeracy skills is justified by the relative importance of quantitative techniques for ICT specialists and by the high correlation (never lower than 0.710) existing among the three measures of cognitive skills provided by PIAAC. The last two lines of column “Numeracy proficiency” in Table 1 show that, on average, ICT specialists scored 306.5 points in the PIAAC numeracy test,

whereas non-ICT specialists scored 267.7 points out of 500, for a differential of 38.8 points. The estimate in Table 3 shows that 24.9 points of this differential depend on a disproportioned concentration of characteristics that favor proficiency in numeracy among ICT specialists. However, the remaining 13.9 points (significant and positive coefficient of variable ICT Specialist in Table 3) represent the better performance that ICT specialist on average provided compared to individuals endowed with similar characteristics. Compared to the rest of the workforce EU ICT specialists

provide a statistically significantly higher level of cognitive skills as proxied by numeracy skills.

Similarly to Table 3, Table 4 reports the outcomes of an OLS regression that tests the determinants of the frequency of soft skills provision. Also in this case the coefficient of variable ICT Specialist is statistically significant. However, its negative sign shows that the higher soft skills declared by ICT specialists (last column in Table 1) are totally due to the heterogeneous distribution of soft skills drivers across the workforce. When compared with individuals with the same

age, gender, education, family background, occupation, employment conditions, and country of residence ICT specialists reveal lower frequency of soft skills provision.

DO EUROPEAN ICT SPECIALISTS EARN HIGHER REWARDS?

The higher educational and professional human capital of ICT specialists is associated with higher hourly and monthly average gross earnings (Table

5). To ensure comparability of data across countries earnings are expressed in US dollars and corrected to account for purchasing power parity (PPP). In addition, they include bonuses for wage and salary earners and self-employed.

As in the case of ICT specialists' skills discussed above the higher earnings observed compared to other employees may depend on two different phenomena. Higher earnings could follow from an over-representation of characteristics

Table 5. Earnings: ICT specialists vs. other workers

Country	ICT Specialist	Hourly Earnings [PPP Corrected \$US]	Monthly Earnings [PPP Corrected \$US]

usually associated with high wages among ICT specialists, such as higher educational qualifications or superior hierarchical positions. However, the higher earnings in Table 5 may also reflect an occupation-specific premium recognized to the unique and scarce capabilities provided by ICT specialists.

Information provided by the PIAAC Survey allows to disentangle the source of the wage advantage of ICT specialists by estimating OLS regressions of a wage equation (Mincer, 1974),

which explains the natural logarithm of wage with the drivers of individual human capital. When statistically significant, the coefficients estimated for independent variables appraise the percent increase of individual wage caused by a unit increase of the corresponding independent variables (McGuinness, 2006). The inclusion of a binary variable that takes value 1 for ICT specialists and 0 for other workers allows assessing the existence of a significant wage premium for ICT professionals.

Table 5 reports the coefficients estimated for two wage equations by means of OLS regressions. In both models the dependent variable is the natural logarithm of hourly gross earnings. Model 1 provides a baseline specification that controls for individual education and educational mismatch, individual experience, and individual-specific, job-specific, and country-specific effects. The latter regressors, always jointly significant, are not displayed in Table 6. Model 2 adds to the independent variables of Model 1 three interactive factors to explore whether years of education, gender, and proficiency in numeracy skills are rewarded differently for ICT specialists compared to the rest of the workforce.

In general terms, Model 1 in Table 6 confirms the findings of previous studies of wage determinants (McGuinness, 2006). However, for the purposes of this contribution the key variable is ICT Specialist. The positive and significant coefficient of this variable shows that, *ceteris paribus*, ICT specialists enjoy 3.4% higher hourly earnings compared to other workers. The estimated average premium is lower than the figures reported in Table 4, according to which the hourly wage premium of ICT specialists averages 37% for all countries (23,7 US\$ per hour for ICT specialists compared to 17,3US\$ per hour for other workers). This outcome suggests that, on average, the overrepresentation of wage-enhancing characteristics among ICT specialists explains 33.6 points of the observed 37% differential. Yet, the remaining 3.4% is the reward recognized to unique and scarce capabilities provided by ICT specialists.

The exam of the coefficients estimated for Model 2 in Table 6 confirms that employers attach a higher value to some individual characteristics of ICT specialists compared to other workers. This is not the case of years of education (non-significant coefficient of interacted variable ICT specialist*Years of education), whereas the wage penalty of female employees more than halves for female ICT specialists as a result of the sum of the negative and significant coefficient of variable

Female and the positive and significant coefficient of the interacted term ICT specialist*Female. If a 10-point increase in the score of the PIAAC numeracy test is associated with a 1% increase of gross hourly wage for all workers, this advantage doubles in the case of ICT specialists, thanks to the composition of the coefficients of variables Numeracy and ICT specialist*Numeracy. In contrast with cognitive skills, soft skills do not impact the earnings of ICT specialists differently

from other workers. When adding an interactive term ICT Specialist*Soft skills to Model 2 the estimated coefficient is not statistically significant.

FUTURE RESEARCH DIRECTIONS

Up-to-date information on the evolution of ICT specialists' skill profiles is needed to design and support educational, vocational, and training programs able to comply with changes in demand requirements. Three main research lines are crucial to improve the quality of available information on ICT specialists and their skills. First, agreement is needed to operationalize a statistical definition of ICT specialists, today still identified based on the only partially overlapped criteria of membership in specific industries or specific occupations. Second, longitudinal datasets focused on ICT specialists are required to assess skills evolution and to avoid estimate biases due to unobserved individual heterogeneity. Third, given the potential of ICTs in supporting economical catch up the collection of statistical information on ICT specialists should extend to developing countries.

CONCLUSION

The European Union frames ICT skills as a crucial resource to prevent the loss of key ICT jobs to other regions of the world (Eurostat, 2015a). Unfortunately, the performance of the EU ICT sector has been lagging behind its main competitors in most recent years (OECD, 2015). To catch up with competitors EU countries need to value and develop the human capital of their ICT specialists. The proposed empirical analyses point out at least three possible paths to pursue this goal.

1. In all examined countries ICT specialists display higher human capital and enjoy better employment conditions. In addition,

the superior cognitive skills of ICT specialists command better earnings. Employment policies should leverage on this evidence to attract high-potential labor inflows.

2. Also after accounting for the heterogeneous distribution of employee-specific and job-specific characteristics ICT specialists confirm to provide higher levels of cognitive skills. In contrast, they provide lower soft skills compared to otherwise similar individuals. Educational curricula and training programs need adjustments to avoid the risk of skill shortage in ICT-complementary skills.
3. Female workers and non-native workers may improve their labor market outcomes by pursuing a career as ICT specialist. Employment policies may focus on these segments of the labor market to enlarge the number of candidates to ICT jobs.

KEY TERMS AND DEFINITIONS

Cognitive Skills: Intrinsic individual characteristics that can be measured by achievement tests and taught in formal educational or training programs.

ICTs: Information and Communication Technologies. ICTs comprise methods and systems to transfer, archive, retrieve, and elaborate information, digital information included.

ICT Specialist: A professional who has the ability to develop, operate, and maintain ICT systems and for whom ICTs constitute the main part of the job.

Job Polarization: Concentration of labor demand towards jobs in the high and the low tails of skills requirements distribution.

PIAAC Survey: International assessment of the competences of adult population run in 22 OECD countries in 2012 within the wider Programme for the International Assessment of Adult Competencies (PIAAC).

Skill Shortage: Difficulty to fill open vacancies due to lack of candidates endowed with relevant skills.

Skills for the Digital Economy: Skills to develop, use, and manage ICT-based products and processes in business and household life.

Soft Skills: Intrinsic individual characteristics hardly measurable by achievement tests. Soft skills are broadly applicable across different job titles, occupations, and industries.

A Trust Case-Based Model Applied to Agents Collaboration

Felipe Boff

Lutheran University of Brazil (ULBRA), Brazil

Fabiana Lorenzi

Lutheran University of Brazil (ULBRA), Brazil

INTRODUCTION

The interaction among people as well as the interaction among systems can, at times, be seen from similar perspectives. People and systems construct their relationship network supported by information. People have the ability to retain information about things and, based on that, pursue their requirements. Computational systems can also function in a similar manner; however, this is highly dependent upon how they were created. As time passes, a person may lose contact with someone or develop stronger ties if they see this relationship as favorable. Systems and agents can also cease to relate to other systems or start new relationships, but, for this, actions external to the agent or system may be necessary.

One of the feelings that can bring comfort to interpersonal relationships is trust. Based on this feeling, people allow other people they trust to participate more frequently or intensely in their lives. The relationship between two systems is treated here as collaboration, where each agent, according to its computational purpose, executes operations requested by other agents. Computational systems, however, can have difficulties in evaluating their collaboration with other systems. Quantifying collaboration as appropriate or detrimental can require complex algorithms and several exceptions to a given rule. The proposal presented here suggests the creation of a method which evaluates the relationship between two agents to generate a rating, called *general trust rating*.

All collaborations between agents are unique and generate equally unique results. These results can be seen as a history of the collaboration between agents. This history is rich in information which can be used to underpin the generation of a trust rating. For this, the information has to be stored. The more information that is stored, the more complex the process of extraction has to be. Due to this, a Case-Based Reasoning approach is used to store this information. The collaboration between agents generates a new case in the case database, which comprises the history of this collaboration. Whether this is beneficial or not for the agent can be concluded by reviewing the whole collaboration history. By using the method developed, the correlation of this history can be quantified, generating a trust rating.

This paper presents a method which was developed to quantify the relationship between agents through the generation of a rating. As in human relations, agents may have a high degree of trust in other agents when the relationship is analyzed from a wider perspective. Nevertheless, the agent is likely to have a different trust rating for specific activities due to the environment it is exposed to or to its purpose. In order to allow this differentiation, the proposed method uses case-based reasoning for each collaboration request to find similar previous collaboration. It selects from this base of previous collaboration cases those that were similar to the current demand, generating a situational trust rating for it. The weighting of the situational with the general trust rating allows

evaluating the collaboration considering a particular situation as well as the history of collaboration between the agents.

In the following sections first we present some related work and how the important points are set in the proposed method. Then we illustrate how the method was implemented, where functionalities are separated into modules so as to provide segregation and isolation of these functionalities: we present the tests that were run and the obtained results that corroborate the efficiency of the method. Finally, we present our conclusions and some future work we have planned.

BACKGROUND

Related Work

The conceptual definition of an autonomous agent is understood as being something that perceives its environment through sensors (physical or virtual) and acts upon this environment through effectors (Russel & Norvig, 2003). These effectors can resolve problems or determine actions, acting on the environment to carry out sets of goals or tasks for which they were designed.

A multi-agent system (MAS) consists of a group of agents hosted in an environment where autonomous agents collaborate with other agents for solving problems (Challenger et al., 2016). Agents can be competitive - when an agent attempts to maximize its performance measures over those of other agents - or cooperative, when the agents function in such a manner that they complete their goals and tasks through the knowledge of other agents.

MAS are exploited in several contexts nowadays to provide e-services, as e-Commerce, e-Learning and so on. Those systems are distributed across the internet and are hosted by different companies or structures. Thus, they have a decentralized control and are subject to constant changes during their operational life. The relationship between these systems requires the existence of components that can interact flexibly in dynamic and uncertain

environments, with the ability to meet their goals or complete their tasks. (Buccafurri et al., 2014).

In both forms of relationship between agents - cooperative and competitive - it is necessary for the agent to have knowledge of the behavior of those agents with which it has a relationship. This necessity becomes of greater importance when the relationship between the agents occurs in open MAS, given that the differences in structures or controls can impact directly on the task results.

Collaboration Between Agents

The collaboration between agents can be defined as the division of a global task, decomposed into a number of agents' subproblems that can be solved efficiently based on the collaboration of agents (Hsieh & Lin, 2014). This definition makes it possible to understand that collaboration between agents has direct impact on the final result of a task.

Even when two agents have exactly the same purpose and receive exactly the same demand, the outcomes can be different. In addition, since they may have different knowledge, they can be hosted in different structures or have different relationships. It is important that, due to this, collaboration is made between agents that possess the best knowledge, the best performance and also the lowest error rate.

The possibility of interaction between ever wider and more disperse systems has resulted in the creation of numerous models of interaction, such as collaboration (Pynadath & Tambe, 2002) and negotiation (Kraus, 2001). However, the application of these models to open MAS has presented a major challenge; each agent can interact with agents of the same or of other categories. In the literature, various interaction paradigms have been defined. Agents can be competitive if they have conflicting objectives and cooperative otherwise (Barbati, Bruno & Genovese, 2012).

All of the interaction models created presuppose that the relationship between systems will result in a common objective and in the same level of information. Nevertheless, in practice, it is almost impossible to obtain an adequate level

of information about the environment or about the interactive properties of the partners, the possible strategies and priorities (Russel & Norvig, 2003).

Trust as a Determinant for Collaboration

Given the context that has been presented, the agents are exposed to elevated levels of uncertainty when taking decisions. Thus, they need to have trust in other agents as a method of reducing the uncertainty associated with interactions in open MASs.

Among the different definitions of trust, the one that follows reflects the reason why it is so necessary for agents to have knowledge of the environment to which they are exposed: "Trust is a belief an agent has that the other party will do what it says it will (being honest and reliable) or reciprocate (being reciprocate for the common good of both), given an opportunity to defect to get higher payoffs" (Ramchurn, Huynh, & Jennings, 2004). The utilization of trust in MAS environments is very diversified in approach (Rosaci, 2012) (Khosravifar et al., 2009) and in the form of definition (Sabater & Sierra, 2005). Even in approaches that support their definition by the same principle, trust has to be quantified as a translation of descriptive variables. By this the theory stated by Marsh (1994) a solid combination of well-defined patterns and suitable calculation approach.

According to Marsh (1994), trust can be separated into three different aspects: *basic*, *general*, and *situational*. Basic trust is a reflection of all the past experience of an agent in any situation - that is, without differentiating between these experiences among interlocutors. General trust represents the trust of an agent in a specific interlocutor, considering all the interactions between these two. Situational trust reflects the trust of an agent in an interlocutor in a specific situation - in this evaluation, only those interactions that are similar to the situation for which the trust rating is desired are considered. These definitions will be detailed later in this paper.

In addition to the separation in three aspects, Marsh chose to treat trust as a numeric interval, in the range $[-1, +1]$. This range represents the possible trust that an agent has in another considering the definitions given in the preceding paragraph. Each of the three different aspects of trust uses the same range.

Two points have to be emphasized with respect to the interval defined by Marsh: 1) distrust and no trust are different states and should be treated differently, in which the value of 0 (zero) in the trust interval does not mean distrust, but that there has been no trust established in the first place. This rating could be the initial value in a relationship; 2) while a rating of -1 reflects total distrust in an interlocutor, the same situation is not possible for a rating of +1, as a value of +1 represents absolute trust or "blind trust", which means this agent is trusted regardless of the situation - something that does not refer to the concept of trust, given that this requires the evaluation of the situation as a presupposition for collaboration. To avoid these problems of interpretation of the trust ratings Marsh created a stratification of trust - somewhat similar to fuzzy logic for trust -, which is presented in table 1.

Table 1. Stratification of trust values (Marsh, 1994)

Value Range	Label
+1	Blind Trust
> 0.9	Very High Trust
0.75 to 0.9	High Trust
0.5 to 0.75	High Medium Trust
0.25 to 0.5	Low Medium Trust
0 to 0.25	Low Trust
-0.25 to 0	Low Distrust
-0.5 to -0.25	Low Medium Distrust
-0.75 to -0.5	High Medium Distrust
-0.9 to -0.7	High Distrust
< -0.9	Very High Distrust
-1	Complete Distrust

These concepts require the agent to be capable of weighting indicators - be they quantitative or qualitative - in a consolidated manner, so as to calculate a trust rating for each agent for each of the basic, general and situational aspects. The ability to consider these indicators is to be found through trust models.

On the basis of calculated trust rating for other agents, an agent can choose to interact with those that have a higher trust rating. On the other hand, a lower trust rating allows an agent to avoid interactions with agents that have these lower ratings. The increase in interaction due to higher trust ratings or the reduction of interaction where the trust rating is low tends to generate a result that better meets the demand.

The Calculation of Trust Rating

The trust model proposed by Marsh (1994) considers only direct interactions between agents. It means that there is no increase or reduction in the trust rating without some collaboration. As previously discussed, the model is divided into three different types of trust: basic, general and situational, with each type having a different formula for evaluation and calculation.

Case-Based Reasoning for the Calculation of the Trust Rating

The use of CBR is directly related to the solution of the problem. CBR uses past experiences for trust have showed good results (Floyd, Drinkwater & Aha, 2014) (Abedinzadeh & Sadaoui, 2014). Problems are solved through the reuse and, at times, adaptation of known solutions to similar problems. The review phase is of great importance to the final results of systems that use this methodology. This phase is identified as essential to the process of human learning: the confirmation of a plausible solution to a problem (Stefan & Weiß, 1991).

This paradigm of human review during the CBR cycle is very important for the system to

learn. However, it requires external interference in the system for the validation of its results.

When the use of CBR systems is evaluated for the measurement of the trust ratings of agents, the first paradigm to be overcome is identified: the need for human interaction in the evaluation of results. In open MAS there are many agents and proportionally many more interactions between them. The need for human evaluation of the trust indicator generates a bottleneck, reducing considerably the effectiveness of a system that had been presumed to be automatic. The existence of previous cases of interaction between two agents can serve as a means of comparison to guide future requirements. It is also possible that past cases can be re-evaluated, allowing their outcome to have a different effect on the result. For example, in the event that a given agent increases its response time on some occasions, this situation will certainly impact on the final result of the required task for a calling agent which should result in a decrease in the trust rating of these agents. However, conventional methods do not consider the complete history of the relationship and do not permit a complete view of the collaboration of these agents. Through the review process of CBR it is possible to see isolated incidents as connected incidents because of their similarities, allowing the trust rating to reflect this situation.

Reuse of Cases Not Only for the Measurement of the Trust Rating

According to Bedi & Vashisth (2014) computing trust is a problem of reasoning under uncertainty, requiring the prediction and anticipation by an agent (the evaluator) of the future behavior of another agent (the target). With the use of CBR it is possible that all interactions be treated as cases and, thus, be stored in the case base. Through the reuse of cases it is possible to calculate the situational trust rating considering only those cases that are similar to the current collaboration, thus foreseeing to predict the agent's behavior.

The approach suggested by Marsh (1994) combined with the CBR approach, allows that the general trust rating of an agent to be high. However, given a particular interaction request, the situational trust rating can be calculated according to the results of the latest interactions in this context and be divergent in relation to the general rating. As an example, a sales agent has a high trust rating for a payment agent, which, in turn, has methods for consulting the scheduled payments. However, interactions directed to this end generate worse results for other agents. Given this situation, despite the global trust rating being high, demands for scheduled payments could be sent to other agents that have better ratings for the case in question.

Method for Calculation of the Trust Rating

The relationships between agents present major challenges that demand a large degree of adaptability of the agents and understanding of the environment to which they are exposed. The method for the calculation of the trust rating proposed in this paper addresses one form of evaluation of the relationship between agents in a multi-agent system. The goal of the proposed method is to provide the agents - in a fast and efficient manner - with a list of trust ratings for the agents available to carry out a requirement. The differential of this method is the evaluation of the general trust rating of an agent in accordance with the cases that represent the relationship with another agent, here called the situational trust rating. Therefore, through a correlation between general and situational trust ratings is achieved a new trust rating based on the overall relationship and similar interactions among agents. This method also provides a differential with respect to the evaluation of relational scenarios between the agents. The collaboration will entitle the evaluation of trust from one agent to others: the *caller* agent (the one who is asking for the collaboration), and the agents that can execute the demand from the

caller. Given that three trust ratings are created: the basic, considering the trust rating of an agent (the caller) to the system; a general, considering the trust of the caller agent in another; and another situational which reflects the trust that *caller* agent has for another in specific situations similar to the desired collaboration.

The general trust rating - which covers all of the interactions between agents - and the situational rating will be considered in the evaluation of the trust relationship of one agent with another. Given this, the method developed allows not only the general relationship between the agents to be considered at all times, but also the calculation to weight the trust rating obtained from similar situations against the required collaboration, inhibiting those cases in which a high general trust rating would prevail over the relationship between the agents. Through the proposed calculation, the system searches for the best collaboration for the situation presented rather than the best collaboration with the best agent.

The collaboration between agents is treated as a case possessing information that permits it to be classified and differentiated with respect to other collaboration demands between the two agents. Figure 1 shows that after each collaboration request, the method will use the information about this collaboration to recalculate the global trust rating between the agents and this update will be done based on the information from the current request weighted against previous cases of collaboration. It means that past cases are relevant to the calculation. This method allows the history in the trust rating to be considered, ensuring that collaboration momentarily rated positive or negative does not distort the trust rating.

The great differential of the proposed method addresses the use of similar cases to the current collaboration request for the calculation of the situational trust rating for the request, considered along with the general trust rating of the agent. The basic process for this calculation is shown in Figure 2, in which the method provides the agents with a means of evaluation that is more directed

Figure 1. Basic process for updating trust ratings. Source: the authors

to the collaboration demands, allowing the trust rating to reflect the effective trust for that agent more precisely given that demand.

The cases are obtained from the collaboration between agents themselves. The second step in the sequence for collaboration shown in figure

Figure 2. Basic process for the calculation of the demand trust rating. Source: the authors

1 indicates the storage of the collaboration in a database. Trust rating needs cases for its validation, but these did not exist yet for a first interaction. Thus, we have a situation of double dependency, in which the trust rating depends on cases and the generation of cases depends on the trust rating. This situation is most likely at the start of a relationship when there are no pre-existent cases. In order to deal with this issue, the initial trust rating may be arbitrated, i.e. originated through the use of the basic trust rating of another agent, permitting the system to consider the agent for the next collaboration request. The adoption of an initial trust rating of zero, that does not indicate distrust has also been set up, but that there has been no trust established yet.

Hierarchical algorithms were considered for the selection of cases that should be used in the calculation of the situational trust rating. They treat the relationship between variables and allow for the creation of new variables based on

information originated from the case itself or even from the systems.

The trust ratings are not calculated in a pairwise manner because all the measures are made by one side (by the *caller* of the collaboration). All calculation considers the results achieved by the *caller* perspective. That means all metric used to measure the trust between *caller* and executor are set and evaluate by the *caller* agent. The system is focused in figuring out the most trustful agents to collaborate from the caller perspective. When collaboration is needed the *caller* agent has a list of agents that can provide that interaction and their respective trust in different perspectives: trust in the agent itself, that is indicated by the general trust which covers all of the interactions between agents; trust in the agent during collaboration similar to the desired one, indicated by situational trust which is measured considering all cases similar to the intended collaboration; and the basic trust, which is the trust of the caller on the network it is

Figure 3. Algorithm flowchart. Source: the authors

exposed. Considering all prior interactions without filtering the executor, the Basic trust indicates if the available network is trustworthy to the *caller* agent. Figure 3 shows the meta algorithm flowchart flowed by the proposed method.

Given that all relations generate new cases, there is a tendency toward the increase of the case base for agents that have high volumes of collaboration. As a means of avoiding a huge case base, a mechanism was created to exclude less expressive or older cases. The mechanism searches for cases that have the least impact on the trust rating, trying to ensure that the withdrawal of cases from the base does not alter the global trust rating. The mechanism also considers the quantity of cases similar to the case being withdrawn, ensuring that unique cases remain in the case base.

As a means of presenting trust as a number that can be subject to calculation, the method was created with two possibilities for demonstrating this value, the first being from an external source - stored together with the case information and referenced in future calculations. The second, who was implemented, was through the indication of a variable that reflects the trust in the agent. For this paper, the variable of response time was selected to indicate trust - how the calculation works will be explained later. It is important to stress that the method constructed could consider more than one variable as determinants of trust, for example response time and number of items returned.

In order to obtain a trust value for a task, agent or method through execution time, the formula constructed considered that all agents have trust 0 at the start of the system. If there was no trust information in the case database then the first collaboration would have a trust of 0.99 if it finished successfully or -1 in the case that it concluded with an error. From the second case, the system will calculate the average execution time for a task, agent and method. On the basis of this calculation there will be a deviation in respect to the collaboration in question to indicate trust. Collaborations with performance slower than average will have reduced trust and collaborations with faster-than-

average performance will have increased trust. Collaborations that result in errors always reduce the trust in proportion to their deviation.

It is important to mention that trust in our approach can be measured in any context. Our approach does not create limitations to any level of evaluation. However, since the system is based on the relationship between *caller* - the agent who is demanding the collaboration - to executor on the service perspective it is more likely to be used on inter-organizational or multi-organizational. In these two approaches the caller agent will always be the organization that evaluates the trust among other company or service. In inter-organizational the system is trying to identify which of its service is the most trustful. In multi-organizational, the executor will be another organization and the caller agent is expanding its evaluation to the market looking for the most trustful organization among several companies that provide the desired collaboration.

Tests and Validation

Several tests scenarios were created to validate the presented method, based on a determined and fictional environment. We created an environment isolated as much as possible from external variables to run the tests. As to simplify test scenarios, the environment was created with two agents (*fCalculadora* and *iCalculator*) with similar purposes - adding two numbers - and the agent caller. The intention of caller's collaboration was to add two numbers. Focusing on situational trust calculation, these scenarios considered fixed values for utility and importance, so the tests showed only the variation in the trust itself.

In each scenario we interfered in a different variable. There is a scenario that we change the day of execution to impact the situational trust. A collaboration performed on Monday may be different from collaboration on Friday; perhaps these are two situational trusts. In another scenario we forced the collaboration to result in an error, this situation has to affect negatively all the trust, in

a higher degree the situational trust, in a median level the general trust and in a lower degree the basic trust. This goal was to prove that trust is a reflection of all interactions, however the impact on the rating will happen accordingly how representative is the case to the trust index (basic, general and situational).

All test scenarios executed had their basic trust rating equal to 0.1546, general trust rating -0.0335973 for the agent *fCalculadora* with method “soma” and for the agent *iCalculator* method “add” the rating was 0.342863. According to the table of stratification trust values, these ratings meant the system had low trust in all its environment, the agent *iCalculator* had a trust rating classified as low medium trust and the agent *fCalculadora* had a low distrust.

The first test scenario aimed to verify the situational trust considering these hypothetical values:

- First sum value: 10.00125;
- Second sum value: 10.002;
- Execution date and time: 11/16/2014 at 08:29:00 PM
- Execution weekday: Sunday.

Those values were considered in the process of retrieving similar cases to this one and are also included in the similarity calculation. Figure 4 shows the result for this test scenario. Through the retrieved cases, the situational trust rating for the “add” method was 0.33, creating a weighted trust of 0.3364315 (the weighted trust is the average between situational trust and general trust). According to the weighted trust, the recommendation was directed to the method “add”. More importantly, this test scenario did not update the case base and, therefore, there were no trust ratings update.

The second test scenario considered the same execution date, but the added values were greatly reduced. Thus, the retrieved algorithm selected different cases from the first test scenario. The following values were considered in this test:

Figure 4. Results obtained from the first test scenario. Source: the authors

```

-----Task Information-----
Task Runtime: 5
Task Trust: 0.192279
-----
Method: add
Method Runtime: 3
Method General Trust: 0.342863
Method Situational Trust: 0.33
Weighted Trust: 0.3364315
-----
Method: soma
Method Runtime: 2
Method General Trust: -0.0335973
Method Situational Trust: 0.23935127
Weighted Trust: 0.10287698
-----Suggested Method-----
|Id: 1 - add
-----
Done!!!

```

- First sum value: 10125;
- Second sum value: 102;
- Execution date and time: 11/16/2014 at 08:29:00 PM
- Execution weekday: Sunday.

The basic and general trust ratings were the same as the first test scenario. Figure 5 shows the results obtained. The main difference from the previous run is the suggested method – “soma”. This happened because of the increase of 247% in the situational trust rating on the suggested method when both runs were compared. In addition, there was a reduction from 0.33 to -0.17134847 in the situational trust rating for the “add” method. This reduction may have happened because either the elapsed time or the error rating from the retrieved case was higher.

For the third test scenario, the same values of the first scenario were maintained, but the execution date and time were modified to the middle of the week. In the first scenario, the weekday of execution was during the weekend and the shift had been moved from the evening to the morning.

Figure 5. Results obtained from the second test scenario. Source: the authors.

Weighted Trust: 0.08575726
-----
Method: soma
Method Runtime: 2
Method General Trust: -0.0335973
Method Situational Trust: 0.5703666
Weighted Trust: 0.26838467
-----Suggested Method-----
|Id: 2 - soma
-----
Done!!!

```

The focus on this scenario was to prove the efficiency of the retrieval algorithm and effectiveness of calculations considering changes that happen in the context of collaboration.

The values considered in this run were:

- First sum value: 10.00125;
- Second sum value: 10.002;
- Execution date and time: 11/19/2014 at 08:29:00 PM;
- Execution weekday: Wednesday.

The results justify the recommendation of the “add” method, but as shown in figure 6 there was a reduction in the situation trust level and weighted trust level of this method. This behavior can be explained by displacement of the execution date. Although the other values were kept, the change in the execution date forces the similarity calculation to adapt its results, so new cases are considered then. This scenario shows how the algorithms have the ability to learn with previous cases.

In the last test we applied the same information used in the previous test. However, we updated the collaboration result as an error. This modification allowed the reduction of the basic and general ratings, as shown in figure 7.

-----Updated Trust-----
Basic Trust: -0.0064342767
Method General Trust: -0.355732
-----
Case inserted in the database
Done!!!

```

An execution with performance lower than the average of the past cases reduces the trust ratings, but this reduction is proportional to the percentage of reduction in the performance. When the collaboration occurs with any error - such as timeout or returned error - the reduction is higher due to all the collaboration reversion in the trust rating. Thus, the greater historical cases based the lower reduction curve.

CONCLUSION

This paper presented a trust case-based model applied in multi-agent environments to deal with the collaboration between agents. This method quantifies agent collaboration and generates trust ratings. Therefore, more efficient collaboration between agents is obtained, improving the overall efficiency of multi-agent systems.

Although Marsh's (1994) definition has more than 20 years, it still presents itself as a powerful approach to deal with the concept of trust in the computational environment. This paper was developed joining solid concepts and an innovative manner to tackle the problems related to the evaluation of agent's collaboration.

Several aspects of the collaboration were represented in the proposed method through the use of different measures for trust. Such as: The basic trust index that considers all collaborations from the caller to the environment. General trust gives the vision of the caller agent to another agent considering all previous collaborations. Situational trust goes another step deeper, considering the trust based on past collaborations similar to the desired one. Those three levels create a great flexibility to represent trust, without creating fixed barriers on qualitative variables.

Due to the heavy need of past information the situational trust was the most challenging measure to be implemented. The approach suggested here by the using of CBR proved very handful since

it created a practical way to evaluate and select the relevant information. Different tests were run, showing that the situational confidence rating is extremely sensitive to the context of the collaboration.

Therefore, the evaluation and selection of past cases are critical components in this method. The correct maintenance in the cases database as well the right approach regarding its indexing process are also crucial for achieving the best results. As noted in the tests, the proposed method could change the way cases were retrieved, adding greater assertiveness and flexibility to the context modification.

FUTURE RESEARCH DIRECTIONS

As a future research, this method can provide information to reputation models and also could be extended to measure trust in a pairwise manner. As developed, the method does not share information regarding their collaboration to other agents. Another improvement can be to allow the executor to evaluate its trust in the caller. Currently, just the caller can evaluate the executor. This extension is somewhat relevant in an environment where the executor does not know the caller. Furthermore, this evaluation of trust would allow the executor to avoid being exploited by the caller.

KEY TERMS AND DEFINITIONS

Case-Based Reasoning: An approach that solves new problems using solutions applied in previous cases.

Collaboration: When two or more agents collaborate to perform a task.

General Trust: Represents the trust of an agent in a specific interlocutor, considering all the interactions between these two.

Multi-Agent Systems: A system composed by agents that are able to interact among themselves and within an environment.

Situational Trust: Reflects the trust of an agent in an interlocutor in a specific situation.

Trust Rating: The level of the trust among the agents.

Trust: A measurable level of the probability which an agent knows that another agent will perform a particular action.

Understanding and Assessing Quality of Models and Modeling Languages

John Krogstie

Norwegian University of Science and Technology, Norway

INTRODUCTION

An important challenge for organizational activity is to effectively represent and transfer *knowledge*. One reason why humans have excelled as species is our ability to create common stories and represent, reuse and transfer this as knowledge across time and space. Whereas in most areas of human conduct, one-dimensional natural language texts are the main way of expressing and sharing knowledge, we see the need for and use of two and many-dimensional forms of knowledge representational to be on the rise. A form of representation which plays an increasingly important role in information systems and enterprise development is *conceptual models* (Krogstie, Opdahl, & Brinkkemper, 2007), which are diagrams expressed in some (semi-) formal visual language (e.g. nodes interconnected with edges), describing some area of interest. In (Krogstie, 2007), the following vision was stated: “Over time the use of modelling will become an established way of expressing knowledge in all fields of human conduct. Everyone (not only expert ‘modelers’) is involved in the process of developing and activating models made in adapted modelling language.” Examples of models could be organization charts, strategy and goal breakdown structures, business process models, or models of the information to be contained in a database. The *quality* of a conceptual model will strongly affect decisions based on the model, and can therefore be of vital importance to the stakeholders.

According to general model theory (Stachowiak, 1973) there are three common characteristics of models: *Representation*, *Simplification* and *Pragmatic orientation*.

- **Representation:** Models represents something else than the model itself.
- **Simplification:** Models possess a reductive trait in that they represent only a subset of attributes of the phenomenon being modelled.
- **Pragmatic Orientation:** Models have a substitutive function in that they substitute a certain phenomenon as being conceptualized by a certain subject in a given temporal space with a certain *intention* or operation in mind.

Thus a model is not just a representation of something else; it is a conscious construction to achieve a certain goal beyond the making of the model itself. Whereas modeling techniques traditionally have been used to create intermediate artifacts in systems analysis and design, modern modeling methodologies support a more active role for the models. For instance in Business Process Management (BPM) (Havey, 2005), Model Driven Architecture (MDA) and Model-driven Software Engineering (MDSE) (Brambilla, Cabot & Wimmer, 2012), Domain specific modeling (DSM) (Kelly & Tolvanen, 2008), Enterprise Architecture (EA) (Lankhorst, 2005), Enterprise modeling (EM) (Sandkuhl, Stirna, Persson & Wißotzki, 2014), Interactive Models (Krogstie & Jørgensen, 2004) and Active Knowledge Modelling (AKM) (Lillehagen & Krogstie, 2002; Lillehagen & Krogstie, 2008), the models are used directly as part of the information system of the organization. At the same time, similar modeling techniques are also used for sense-making and communication, model simulation, quality assur-

ance, and requirements specification in connection to more traditional forms of information systems and enterprise development (Krogstie, Dalberg & Jensen, 2008).

Since modeling techniques are used in such a large variety of tasks with different goals, it is hard to assess whether a model is sufficiently *good* to achieve the goals. To provide guidance in this process, the latest version of *SEQUAL*, a framework for understanding quality of models and modeling languages, will be presented in this chapter.

BACKGROUND

Since the early 90ties, many researchers have worked on quality of models. Work on *SEQUAL* can be traced back to at least 1993 (Lindland, 1993). Sindre and Lindland in particular collaborated on the next step (Lindland, Sindre & Sølvsberg, 1994). Although an elegant framework which was easily applicable for understanding important aspects of quality of models, several other works pointed to the need for extending the framework. Important inspirations in this regard was the work on 3 dimensions of requirements engineering (Pohl, 1993), work related to the semiotic ladder presented in early versions of the IFIP 8.1 FRISCO framework (Lindgren, 1990) and work on social construction of ‘reality’ and models thereof of the domain, which is typically not as ideal and objectively given in practice that as the original framework took as an outset (Berger & Luckmann, 1966). Specifically the framework of Pohl also pointed to the need for achieving *agreement* among the stakeholders of the model.

These extensions, in addition to a specific focus on requirements specification models resulted in the framework presented in (Krogstie, Lindland & Sindre, 1995). At the same time Shanks and Moody (Moody & Shanks, 1994) started their work on quality of data models. Becker, Rosemann and Schütte (1995) focused on the quality of process

models. Later a number of other researchers, e.g. (Nelson, Poels, Genero & Piattini, 2011) have worked within this area.

In hindsight the work done on *SEQUAL* can be framed as design science research (Hevner et al, 2004), with the quality framework as the core artifact. Whereas the early validation was primarily analytical, later work e.g. together with Moody (Moody, Sindre, Brasethvik & Sølvsberg, 2002) also included empirical evaluations, and practical applications of the framework have been reported in (Heggset, Krogstie & Wesenberg, 2014; Heggset, Krogstie & Wesenberg, 2015b). The framework has been developed through a number of iterations, and have also in some cases been established as part of the knowledge base e.g. in the development of a framework for quality of maps (Nossum & Krogstie, 2009). The current version of the framework is described in (Krogstie, 2012a) where also newer work on quality of modeling languages (including the work presented by Moody (2009)) is incorporated.

To summarize, *SEQUAL* has three unique properties compared to the early work on quality of models:

- It distinguishes between quality characteristics (goals) and means to potentially achieve these goals by separating what you are trying to achieve from how to achieve it.
- It is based on a constructivistic worldview, recognizing that significant models are usually created as part of a dialogue between the many stakeholders involved in modelling, whose knowledge of the modelling domain changes as modelling takes place.
- It is closely linked to linguistic and semiotic concepts. In particular, the core of the framework including the discussion on syntax, semantics, and pragmatics is parallel to the use of these terms in the se-

Figure 1. SEQUAL framework for discussing quality of models

miotic theory of Morris. Also the work in FRISCO on the semiotic ladder took the work of Morris as an outset, but has extended this with physical, empirical, and social aspects which we have adapted.

FRAMEWORK FOR QUALITY OF MODELS

The current framework is illustrated in Figure 1. Quality has been defined referring to the correspondence between statements belonging to the following sets (the sets depicted as ellipses):

- **G**, the set of goals of the modeling task.
- **L**, the language extension, i.e., the set of all statements that are possible to make according to the rules of the modeling languages used.
- **D**, the domain, i.e., the set of all statements that can be stated about the situation.
- **M**, the externalized model itself.

- **A**, the part of the model that can be accessed by one or more actor, actors being either persons and tools.
- **K**, the explicit knowledge relevant to the domain of the audience.
- **I**, the social actor interpretation, i.e., the set of all statements that the audience interprets that an externalized model consists of.
- **T**, the technical actor interpretation, i.e., the statements in the model as ‘interpreted’ by modeling tools.

The main quality types as illustrated as relationships in Figure 1 are:

1. Physical quality: The basic quality goal is that the externalized model **M** is available to the relevant actors **A**.
2. Empirical quality deals with comprehensibility when a visual model **M** is read by different social actors. Before evaluating empirical quality, physical quality should be addressed.

Figure 2. Seven areas of language quality

3. Syntactic quality is the correspondence between the model M and the language extension L . Before evaluating syntactic quality, physical quality should be addressed.
4. Semantic quality is the correspondence between the model M and the domain D . This includes both validity and completeness. Before evaluating semantic quality, syntactic quality should be addressed. Domains can be divided into two parts, exemplified with a software requirements model:
 - i. Everything the computerized information system (CIS) is supposed to do (for the moment ignoring the different views the stakeholders have on the CIS to be produced).
 - ii. Constraints on the model because of earlier baselined models such as system level requirements specifications, enterprise architecture models, statements of work, and earlier versions of the requirement specification model to which the new requirement specification model must be compatible.
5. Perceived semantic quality is the similar correspondence between the social actor interpretation I of a model M and his or hers current knowledge K of domain D . Before evaluating perceived semantic quality, pragmatic quality (see below) should be addressed.
6. Pragmatic quality is the correspondence between the available part of the model M (i.e. A) and the actor interpretation (I and T) of it. One differentiates between social pragmatic quality (to what extent people understand the model) and technical pragmatic quality (to what extent tools can be made that can interpret the model). Before evaluating pragmatic quality, empirical quality should be addressed.
7. The goal defined for social quality is agreement among social actor's interpretations (I). Before evaluating social quality, perceived semantic quality should be addressed.
8. The deontic quality of the model relates to that all statements in the model M contribute to fulfilling the goals of modeling G , and that

all the goals of modeling *G* are addressed through the model *M*. In particular, one often includes under deontic quality learning and domain change.

Language quality goals are looked upon as means in the framework. 7 areas of language quality are differentiated as illustrated in Figure 2:

1. Domain appropriateness. This relates the language and the domain. Ideally, the conceptual basis must be powerful enough to express anything in the domain, not having what (Wand & Weber 1993) terms construct deficit. On the other hand, you should not be able to express things that are not in the domain, i.e. what is termed construct excess (Wand & Weber 1993). Domain appropriateness is primarily a mean to achieve semantic quality.
2. Ontological appropriateness. Whereas domain appropriateness discusses the languages appropriateness relative to a particular domain, when discussing expressiveness in general, one might want to do that relative to some general framework or ontology developed for the field. Any modeling approach or perspective taken includes some level of ontological commitment, and general discussions on construct deficit and excess is typically done relative to some existing ontology.
3. Comprehensibility appropriateness relates the language to the social actor interpretation. The goal is that the participants in the modeling effort using the language understand all the possible statements of the language. Comprehensibility appropriateness is primarily a mean to achieve empirical and pragmatic quality.
4. Participant appropriateness relates the social actors' knowledge of the modeling language (i.e. do the participants know the language being used). Participant appropriateness is primarily a mean to achieve semantic and pragmatic quality.
5. Modeler appropriateness: This area relates the language extension to the knowledge of the modeler. The goal is that there are no statements in the explicit knowledge of the modeler that cannot be expressed in the language. Modeler appropriateness is primarily a mean to achieve semantic quality.
6. Tool appropriateness relates the language to the technical audience interpretations. For tool interpretation, it is especially important that the language lend itself to automatic reasoning. This requires formality (i.e. both formal syntax and semantics being operational and/or logical), but formality is not necessarily sufficient, since the reasoning must also be efficient to be of practical use. This is covered by what we term analyzability (to be able to exploit any mathematical semantics efficiently) and executability (to be able to exploit any operational semantics efficiently). Different aspects of tool appropriateness are means to achieve syntactic, semantic and pragmatic quality (through formal syntax, mathematical semantics, and operational semantics respectively).
7. Organizational appropriateness relates the language to standards and other organizational needs and constraints within the organizational context of modeling. These are expected to support deontic quality in particular to support efficient modeling within the organization.

Issues and Recommendations for Dealing With These Issues

Whereas SEQUAL over the year has evolved to a very comprehensive framework, it has been found hard to understand and use in practice both by practitioners and researchers in the field (Reijers, Mendling and Recker 2010). One reason that the framework is complex to use in practice is that it

is very generic. Inspired by (Moody, 2009), suggesting the need for an inheritance hierarchy of quality frameworks, we have started to develop a number of specialized version of SEQUAL applicable for specific types of modeling, see e.g. the specialization of SEQUAL for business process models in (Krogstie, 2012b, Krogstie, 2016).

As illustrated in fig. 3 below there are a number of specializations of SEQUAL. As with GoM (Becker et al. 1995), we have a first level meant to be relevant for all node-edge-oriented models (SEQUAL-GEN). A second level looks on a particular type of models. Finally one can have specific guidelines on an even more detailed level, e.g. for business process modelling using BPMN. In real-world modelling activities we find that all quality levels are important, but the *weight* on different levels is different based on different goals of modelling.

Basis for the different specializations can be found in (Krogstie, 2012a):

- **SEQUAL- SRS:** Software requirements specifications (Krogstie, 1999; Krogstie, 2001), including quality of goal models (Krogstie, 2008)
- **SEQUAL - DM:** Data models (Krogstie, 2013a)
- **SEQUAL - DQ:** Data quality (Krogstie, 2013b) and data integration quality (Krogstie, 2015))
- **SEQUAL - IM:** Interactive models (Krogstie & Jørgensen, 2002)
- **SEQUAL - EM:** Enterprise models (Krogstie & Arnesen, 2004)
- **BPM:** Business Process Models (Krogstie, 2012b; Krogstie, 2016), in particular BPM using BPMN (Recker, Rosemann & Krogstie, 2007, Aagesen & Krogstie 2010, Aagesen & Krogstie, 2015)
- **SEQUAL - ONT:** Ontologies (Hella & Krogstie, 2010)

Figure 3. Specialization of SEQUAL based on modelling perspective

Table 1. Types of models according to temporal aspects and purpose

Type of Model	Past	Present	Future
Ideal model	Ideal model of the past	Reference model	Ought-to-be model
Simulated model (what-if)	Possible model of the past	Possible model	Possible model of the future
Model espoused	As-was model	As-is model	To-be model
Model in use	Actual as-was model	Actual as-is model	Workaround model
Motivational model	Past burning-platform model	Burning platform model	Burning platform model

- **SEQUAL - MDSD:** Models used in Model-driven Software Development, with a focus on quality of UML-models (Krogstie, 2003)
- **MAPS - MAPQUAL:** (not in the figure) (Nossum & Krogstie, 2009)

Another dimension of specialization relates to the type of model. Traditionally, one have mainly differentiated between as-is (descriptive) and to-be (prescriptive models). Recent work (Fossland & Krogstie, 2015) has illustrated the need for a larger set of model types. In Table 1, we list relevant situations, along the temporal and ontological axes.

First of all models can be of past situations, the present, or a potentially future situation. One look here primarily at the present and future, noting that in several areas, also to keep track of the processes used in the past is important, e.g. in areas where compliance is important and where one can get into situations where the authorities questions the adherence to compliance rules in the past. Models can at all temporal stages be looked upon as being

- **Ideal:** A model of an ideal situation in the area, ignoring contextual restrictions such as legacy systems and installed base.
- **Simulated:** A model that differs in some way to the actual state-of-things, e.g. to be able to play what-if analysis.
- **Model Espoused:** The official model in a restricted area.

- **Model in Use:** How the situation actually is (or was). This should ideally not be so different from the model espoused, but in practice we often experience this.
- **Motivational Model:** A simulation which depicts a defensive approach i.e. what happen if nothing is done. This is often termed the burning-platform model.

FUTURE RESEARCH DIRECTIONS

By making the framework more operational and instrumental, with precise guidelines that can be implemented in modeling tools to directly support the modeling process, and with stronger validation in real, industrial case studies one can take the SEQUAL-framework a great leap forward

Secondary objectives to achieve this are to validate and extend the existing SEQUAL framework, in particular to also support the process of modeling to end up with and evolve models of high quality. In particular to extend the framework to support the process of

- Enterprise modeling, including business process modeling and evolution of interactive models.
- Requirements modeling, including the integrated representation of functional and non-functional requirements. Business process models can also play a role here.
- Improve modeling approaches in enterprise modeling and requirements modeling to take these extension into account.

An appropriate methodology for this type of research is design science research (Hevner et al., 2004) which aims to improve or extend human and organizational capabilities by building new artifacts. Traditionally, four types of artifacts are described; constructs, models, methods and instantiations. A framework for design science is presented by Peffers et al. (2006). In future research on quality of models, we propose in particular to use the following research methods:

- Experiments with individual modelers, investigating how they develop models on a limited domain. We will follow an experimental approach for controlled experiments (Gopalakrishnan, Sindre & Krogstie, 2012) using tools such as Cheetah (Pinggera et al., 2012) that can track detailed modeling activities. From literature (Krogstie, 2012a; Pinggera et al., 2012) starting hypothesis for this setting exist, thus we will first have an objective-centered initiation. When tools and methods are developed to support this modeling-setting, studies having a design and development centered initiation can be performed.
- Group experiments, investigating how groups of modelers with different expertise jointly develop models on open problem areas. Participatory modeling (Gjersvik et al., 2004, Sandkuhl et al, 2014) can be done with a main modeler as in socio-technical walkthrough (Prilla & Jahnke, 2012) using a traditional tool (like Cheetah), or with parallel input from all the participants, in which collaborative tools like CubeBPM is appropriate (Nolte et al 2015). We are currently experimenting with these types of tools, but will need to start out with a problem-centered initiation of the research.
- Longitudinal case-studies of modeling in practice, studying the modeling process of collaborators already applying the core SEQUAL framework (e.g. Statoil (Wesenberg, 2011, Heggset, Krogstie &

Wesenberg, 2015a)). The first phase of this will have a problem-centered initiation, whereas we in the end hope to have research being initiated by external clients, evaluating the results.

CONCLUSION

More active approaches to the use of models in IT and enterprise development are increasing. In enterprise modeling and process modelling in particular one aim at representing knowledge in a format available for a wide variety of stakeholders. These techniques are being taken into use to an increasing degree in areas such as health care, public administration, the oil and gas industry, the building industry, defense, and higher education to make it possible to be able to manage the increased usage and dependency on ICT. One striking aspect is that the number and variety of stakeholders that will need to relate to models increase. Given the increased educational level in most countries, with an increasing group of people with master degrees, it is not unlikely that also more people will be able to relate to these types of abstractions, given that one of the things that you are exposed to in a master study of most types, is how to deal with abstractions. To reach the vision of modeling of the people, by the people, for the people (Krogstie, 2007), visual modeling must become as easy for e.g. designers and engineers as scribbling in order for them to express their knowledge while performing work, reflecting on this for learning and excelling in their roles. This will also enable users to capture contextual dependencies between roles, tasks, information elements and the views required for performing work without having to go through traditional systems developers to have enhanced support for their work. The importance on supporting judgment on quality of these models will thus increase, and also the usefulness of frameworks for quality of models and modeling languages such as SEQUAL.

KEY TERMS AND DEFINITIONS

Analysis Model: A model developed to learn all aspects of a problem domain to determine the best way to solve a specific set of user needs.

Conceptual Model: Models in some (semi-) formal visual modeling language describing some area of interest.

Design Model: A model developed to represent the optimal technical solution of a specified user need (as represented in a requirements model).

Enterprise Model: A model with similar abstraction level as an analysis model meant to capture the totality of relevant aspects for enterprise development.

Model: An abstraction represented in a modeling language.

Modeling Language: A language (i.e. a set of symbols, and rules for how to combine these symbols) to represent knowledge.

Requirements Model: A model to represent the external requirement to a system without taking into account how the system looks inside.

Visual Modeling Language: A diagrammatic modeling language, i.e. where the models made in the language are 2-dimensional diagrams.

Utilizing Information Science and Technology in Franchise Organizations

Ye-Sho Chen

Louisiana State University, USA

INTRODUCTION

Franchising involves with granting and receiving business rights. The one granting the business rights is called the *franchisor* and the one receiving the right to operate in accordance with the rules is called the *franchisee* (Justis & Judd, 2002). Information technology (IT) has been widely used in today's businesses. In his best seller, *Business @ the Speed of Thought*, Bill Gates (1999) wrote: "Information Technology and business are becoming inextricably interwoven. I don't think anybody can talk meaningfully about one without talking about the other." Thus, to see how IT is used in franchising (Repack & Repack, 2010), one needs to know how franchising really works. The objective of this paper is to propose an attention-based IT infrastructure that is grounded in the information science of cultivating the relationship building between the franchisors and their franchisees which will ultimately lead to the success of the franchise organizations.

BACKGROUND

In addition to the popular growth strategy for many businesses, franchising has emerged over the years as a pathway to wealth creation for entrepreneurs (Justis & Vincent, 2001). This paper first discusses the information science of franchising, including the day-to-day operations at both the franchisor headquarters and the franchisee outlets; the franchisor/franchisee relationship and the essential indicators needed to pertain and flourish the good relationship; and the inevita-

bility of collaborative learning and innovation, which leads us to the discussion of the working knowledge development among the franchisor and the fellow franchisees (Dickey, 2003). Second, we discuss that the proposed attention-based IT infrastructure will enable the knowledge sharing and dissemination between the franchisor and the franchisee (Dixon & Quinn, 2004); and suggest outsourcing the initial architectural stages of the IT infrastructure to trusted applications service providers.

UNDERSTANDING THE FRANCHISOR

In this section we examine the day-to-day operational activities at the franchisor headquarters. Figure 1 illustrates the interactions of the franchisor with all four of its entities: business units & customers, prospective franchisees, suppliers, and government; as well as performing relevant activities (represented by rectangles): marketing its products and services, assisting in creating distinguished brand names indispensable in attracting new customers, selling to the franchisees, and handling the diversified financing quandaries.

The franchisor headquarters is required to provide both initial and ongoing support/service to all business units (Lindblom & Tikkanen, 2010). Business units & customers here include company units, all of the start-up, established and mastered franchisees, the co-branded units, and customers & social media. Among the six different types of business units & customers, the franchisor needs to have intense concentration on supporting the

Figure 1. Understanding the Franchisor Learning Process

start-up franchisees, since a good start is as efficient as the half way completion of any task. On the other hand, established and mastered franchisees are the ones in need of appealing incentives (e.g., having cobranded units) in order to encourage growth and expansion. Company units are typically used as role models for the franchisees. To expand the business, the franchisor ought to select and contact the prospective partners (franchisees). The partner selection process is crucial to the success of franchising and requires exceptional attention. Prospective franchisees can be contacted through: leads, referrals, consumers, community and media, public services, and international contacts. Franchise suppliers can be anywhere from products and

goods distributors up to business service providers, such as real estate agents, human resources providers, uniform vendors, marketing and advertising agents, trade show and exposition organizers, accountants, information systems vendors, insurance providers, attorneys, translators, and many others. Franchisors also need to comply with regulations that govern the sales of the franchises and business transactions in the places where the business located. The overall legal landscape of franchising is complex which includes: federal, state, and international taxes; local, regional, and global laws; insurances, such as workers compensation; possibilities of litigations from government, customers, and franchisees; and supports for international expansion.

As is seen in Figure 1, the franchisor interacts with various business entities and conducts various deeds to fulfil his/her obligations. Moreover, the franchisor goes through a learning process, composed of five stages (Justis & Judd, 2002): (1) Beginner – learning how to do it; (2) Novice – practicing doing it; (3) Advanced – doing it; (4) Master – teaching others to do it; and (5) Professional – becoming the best that you can be. Once attaining the advanced stages of development, most preceding struggles have been overcome. However, further convoluted and challenging enquiries will arise as the franchise continues the expansion. This is especially factual once the system reaches the “Professional” stage, where various unpredicted and intricate problems could arise. Bud Hadfield (1995), the founder of Kwik Kopy franchise and the International Center of Entrepreneurial Development, explained it the finest: “The more the company grows, the more it will be tested.” To capture the franchisor learning process in Figure 1, a counter-clockwise round arrow is used in describing the five stages. It depicts the increasing intensity of learning in every stage as the franchise struggles to survive and thrive. In addition, a dashed circle around the franchisor learning process denotes that the learning process is without limits. For example, as the system expands, the real estate sub-activity will become much more complex, since the quandary of territory encroachment becomes more significant and harder to manage.

UNDERSTANDING THE FRANCHISEE

As illustrated in Figure 2, the franchisee sells to customers, perform marketing and advertising activities, handle financial/accounting issues, and manage sales people (Paswan & Wittmann, 2009). Akin to the franchisor, the franchisee outlets (shortened form, franchisee) work together with four entities: customers, franchisor headquarters, suppliers and government. The franchisee custom-

ers are divided into six categories and consist of potential, infrequent, frequent, online, co-branded, and social media. Supports from the franchisor headquarter may include demonstrations from field representatives, training and continued education from the management groups, in addition to discussion forums and distance learning. Suppliers of the franchisee are similar to those of the franchisor. They include both products and goods distributors, business service providers such as real estate agents, human resources providers, uniform vendors, marketing and advertising agents, trade shows and exposition organizers, accountants, information systems vendors, insurance providers, attorneys, translators, and others. The franchisee is regulated by the franchising laws at local, state, and federal level. The regulatory framework contains of: federal, state, and international taxes; local, regional, and global laws; insurances such as workers compensation; possibilities of litigations from government, customers, and franchisees; and support for international expansions.

Developing a high-quality “family” relationship between the franchisor and the franchisee is believed to be the most significant factor for the success of a franchise (Justis & Judd, 2002). To understand how the relationship is developed, one needs to know the franchisee learning process as depicted in Figure 2 (Schreuder, Krige, & Parker, 2000):

- **The Courting Phase:** Both the franchisee and the franchisor are eager with the relationship. This typically corresponds to the Beginner stage of the franchisee.
- **The “We” Phase:** The relationship starts to deteriorate, but the franchisee still values the relationship. This typically corresponds to the Novice stage of the franchisee.
- **The “Me” Phase:** The franchisee starts to question the reasons for payments to their franchisors. They may start to think that the success so far is purely of his/her own work. This typically corresponds to the advanced stage of the franchisee.

Figure 2. Understanding the Franchisee Learning Process

- **The Rebel Phase:** The franchisee starts to challenge the restrictions being placed upon. This typically corresponds to the Master stage of the franchisee. The rebel ones tend to be those who know the system very well and are capable of influencing others to follow them.
- **The Renewal Phase:** The franchisee realizes that the “win-win” solution is to continue teaming up with the franchisor to develop the system. This typically corresponds to the Professional stage of the franchisee.

Thus, the major challenge for the franchisor is to turn a “Rebel” franchisee into the “Renewal” one. A viable solution for the franchisor is to provide a learning and innovative environment

where the franchisee can continue contributing to the growth of the system. Successful collaborative learning and innovations will provide a strong incentive for the Professional franchisees to continue their Renewal relationship with the firm, which in turn will have positive impact on maintaining the good relationship with other franchisees and recruiting new ones. On the other hand, constant failures in this stage will intensify the Rebel franchisees to desert the firm, which in some cases lead to the demise of the franchise. To capture the franchisee learning process in Figure 2, a counter-clockwise round arrow is used in describing the five stages. It depicts the increasing intensity of learning in every stage as the franchisee struggles to survive and thrive. In addition, a dashed circle around

Figure 3. Understanding the Franchisor/Franchisee “Family” Relationship

the franchisee learning process denotes that the learning process is without limits.

DEVELOPING THE FRANCHISOR/FRANCHISEE FAMILY RELATIONSHIP

As the franchisor/franchisee progresses through the learning process, the good relationship gradually develops a mutual influencing process (Justis & Vincent, 2001), depicted in Figure 3 with a bi-directional arrow. In the figure, it shows that the franchise system is operated in the dynamic business environment of global, national, regional, and local communities. The “family” relationship is developed through a mutual learning process of person-centric relationship building. By going through the processes of learning and influencing, both the franchisor and the franchisee gain the progressive working knowledge of relationship management with the consumers and suppliers. The franchisor and the franchisee in Figure 3 are surrounded with dashed lines, indicating that there is no limit to the learning process.

Figure 3 shows the actual usage of IT in the franchise business. For instances, ERP-systems are used in the value chain in franchise business,

including Point-of-Sales systems (Tang & Lee, 2008) used at the store-units to manage the tasks of consumer relationships; and Electronic-Data-Exchange systems used in the supply chain to manage the tasks of supplier relationships (Jun & Xi, 2009). Figure 3 also provides a good impression over IT used in the franchise business and ultimately a good starting point for those interesting in starting a franchise business. Figure 3 also shows how the actual usage of IT in the franchise business differs from the ones used in other industries such as banks or car producers. That is, IT in franchising focuses more on managing and perfecting the franchisor-franchisee relationship through mutual learning process.

Lying behind the successful collaboration is the working knowledge of the franchise firm. Knowledge is defended as “a justified personal belief that increases an individual’s capacity to take effective action.” (Alavi & Leidner, 1999). Knowledge becomes “working” when the action produces results. When knowledge produces results, the personal confidence strengthens, intensifies, and justifies. The more superior the individual’s capacity becomes, the better results are attained. This spiral-up cycle of working knowledge development is very important in the context of franchising (Paswan, Wittmann, &

Figure 4. Developing the Franchisor/Franchisee “Family” Relationship

Young, 2004). Figure 4 shows that the development process is incrementally developed through the five stages of the spiral-up learning process for the franchisor and the franchisee respectively.

The foundation of the learning process is the capability of sharing and coaching the working knowledge throughout the franchise system (Windsperger & Gorovaia, 2011). The process of mutual influencing for knowledge dissemination consists of five steps (Justis & Vincent, 2001): (1) Knowledge, the proven abilities to solve problems in the franchise environment; (2) Attitude, constructive ways of presenting and sharing the working knowledge; (3) Motivation, incentives for learning or teaching the working knowledge; (4) Individual Behavior, the strengths of the participants to learn and enhance the working knowledge; and (5) Group Behavior, collaborative ways to create, disseminate, and manage the hard-earned working knowledge. The franchisor/franchisee

“family” relationship building in Figure 4 is also surrounded with dashed line, denoting that the relationship is enlarged and expanded without limits as the franchisee incrementally learns the working knowledge through the influencing of the franchisor and the fellow franchisees. By going through the processes of learning and influencing, both the franchisor and the franchisee progressively gain the working knowledge and manage the franchisor/franchisee family relationship efficiently and effectively.

AN ATTENTION-BASED IT INFRASTRUCTURE IN FRANCHISE ORGANIZATIONS

In an information-rich world, Herbert Simon (Nobel laureate in Economics in 1978) wrote: “a wealth of information creates a poverty of atten-

Figure 5. An Attention-based IT Infrastructure in Franchise Organizations

tion.” (Simon, 1971) As such, the “proper aim of a management information system is not to bring the manager all the information he needs, but to recognize the manager’s environment of information so as to reduce the amount of time he must devote to receiving it.” (Simon, 1971) From the discussions above regarding the information science of franchising, it is obvious that an attention-based IT infrastructure in franchising shall be one devoted to enabling the building of a good “family” relationship between the franchisor and the franchisee. In Figure 5, we propose such IT architecture (Chen, Chen, & Wu, 2005, 2007) for franchise organizations to manage the immense information produced by the firms.

The architecture, adapted from Gates’ Digital Nervous Systems (1999), consists of the following four layers:

- **Empowerment and Collaboration:** Point-of-sale and office management systems are used to empower the franchisees (Chen, Justis, & Chong, 2002). Internets, Extranets, and Intranets networking the franchisor, the franchisees, customers and

suppliers are deployed to improve collaboration (Chen, Chong, & Justis, 2002).

- **Business Intelligence:** Data warehousing and data mining techniques are used to convert volumes of data into reports and benchmarks for management to glean business intelligence (Chen, Justis, & Watson, 2000; Chen, Justis, & Chong, 2008; Chen, Zhang, & Justis, 2005). Both Empowerment and Collaboration and Business Intelligence are enabled by technology networks with the objective of identifying the good, the bad, and the ugly in the system to gain the attention of the decision makers (Chen, Liu, Zeng, & Azevedo, 2012).
- **Working Knowledge Management:** Intranet-based systems consisting of the skills of coaching/influencing others and working knowledge profiles (Chen, Hammerstein, & Justis, 2002) are implemented for knowledge sharing and learning within the franchise business. A Distance-Learning curriculum (Chen, Chong, & Justis, 2000) of working knowledge modules can also be deployed. The working knowledge management is

empowered by social networks with the objective of transforming the bad to the good (Chen, Seidman, & Justis, 2005).

- **High Value Strategy:** Value networks (Chen, Justis, & Wu, 2006) are developed with the goal of improving working knowledge profiles and applying effectual reasoning principles (Chen, Yuan, & Dai, 2004) to create high value strategy for business opportunities (Chen, Justis, & Yang, 2004).
- **Strategy Execution:** The new strategy is executed by empowering decision makers in their collaborations (Chen, Justis, & Wu, 2008) via the responsive networks.

To demonstrate how the attention-based IT infrastructure is related to the activities of the franchisor, the franchisee (shown in Figures 1 and 2), and the “family” relationship building (shown in Figures 3 and 4), we show in Figure 6 the character of the business process, the information flow in the franchise business, and clarify the rationale behind the necessity of the attention-based IT infrastructure. The foundation of the architecture, adapted from Inmon (1996), consists of four levels: (1) data collected from the empowerment and collaboration activities of the franchisor (Figure 1) and the franchisee (Figure 2), including business legacy data, units operational data, social networks data, external benchmarking data, crowds & networks of data; e-business strategy shall be one empowering the franchisor and the franchisees to do their activities (Chen, Chong, & Justis, 2002); (2) reconciled data in the franchise data warehouse (Chen, Justis, & Watson, 2000), including franchise data warehouse and meta data; (3) derived data residing in data marts based on various franchisee-centred segmentations such as franchise development and support; and (4) business intelligence presentations and reports generated from analytical data analysis; for example, management reporting and benchmarking could be produced by online analytical processing (OLAP) periodically which periodically may lead

to more proactive analysis of top/low performer attributes using the data mining techniques (Chen, Justis, & Chong, 2008).

The business intelligence reports will help the franchise system to identify key top performers and their success attributes. With their involvement, working knowledge profiles can be developed and dissimilated throughout the knowledge networks of the business using coaching/influencing techniques (Chen, Hammerstein, & Justis, 2002). The top of Figure 5 depicts such a knowledge sharing and dissemination idea described in Figure 3 in detail. There are four franchisees (A - D) in the figure. Each franchisee (a dot) has his/her personal knowledge network (arrows pointing out of the dot). The knowledge network may include the customers' likes and dislikes, the kind of employees to hire, the competitors' and suppliers' pricing strategies, the social needs in the local community. Each franchisee is surrounded with a circle with dashed lines, meaning there is no limit to the personal knowledge network. Supposing franchisee A is the top performer and is charged and rewarded with coaching/influencing other franchisees to survive and thrive. Thus, clusters (connected dots) of knowledge network are formed and surrounded with a circle with dashed lines, meaning there is no limit for improving and leveraging the assets of the business (Chen, Justis, & Yang, 2004). Using the attention-based IT architecture as a guide, we recommend franchise organizations to outsource IT in the first two layers to application service providers (ASPs) (Chen, Ford, Justis, & Chong, 2001). The concept of subscribing IT services through ASPs has special appeal in the franchising industry because an ASP can duplicate success for former similar franchises quickly and economically.

Figure 6. Implementing the Attention-based IT Infrastructure in Franchising

FUTURE RESEARCH DIRECTIONS

With the popularity of using social media to develop social networking for growth (Perrigot & Pénard, 2013), one may find amount of data available on social media sites such as Facebook and Twitter. The need for analysing the “big data” to identify meaningful patterns for useful decision making (He et.al, 2013) is becoming a necessity, especially for those franchises interested in going abroad, e.g., to emerging markets such as BRICS (Brazil, Russia, India, China, and South Africa). Developing soft landings curricu-

lum (Chen, Watson, Liu, Cornachione, and Wu, 2010; Chen, Watson, and Azevedo, 2011) using the resource-based strategy (Chen, Watson, and Azevedo, 2013; Chen, Watson, Cornacchione, and Azevedo, 2013) is a smart strategy for franchising in emerging markets.

CONCLUSION

Franchising has been popular as a growth strategy for small businesses; it is even more so in today’s global and e-commerce world (Chen & Wu, 2007).

Although IT is quite important in franchising, IT researchers have largely ignored this arena. One major reason is that few IT researchers are vested in the knowledge of how franchising functions, and without this intimate knowledge it is difficult to implement effective IT systems. Based on years of academic and consulting experiences in franchising and IT, an effective framework of IT in franchising is proposed. At the heart of the framework is to manage working knowledge and use IT to build up the “family” relationship between the franchisor and the franchisee.

KEY TERMS AND DEFINITIONS

Attention-Based IT Infrastructure: An IT infrastructure which is able to sort through volumes of data and produce right information at the right time for the right persons to consume.

Franchisee Life Cycle: The stages a franchisee goes through in the franchise system: Courting, “We”, “Me”, Rebel, Renewal.

Franchisee: The individual or business who receives the business rights and pay the royalties for using the rights.

Franchising: A business opportunity based on granting the business rights and collecting royalties in return.

Franchisor/Franchisee Learning Process: The stages of learning, including Beginner, Novice, Advanced, Master, and Professional.

Franchisor/Franchisee Relationship Management: The vital factor for the success of a franchise, including: Knowledge, Attitude, Motivation, Individual Behavior, and Group Behavior.

Franchisor: The individual or business who grants the business rights.

Robert Morris University, USA

INTRODUCTION

Computer Fraud

Computer fraud and hacking attempts have been publicized for more than a century. Although customers only think of computers and smart-phones being hacked, there are examples in the early 19th century where phone lines were hacked. Cybercrime is a fast growing area and has drastically increased over the years. Its business model is evolving and the market is profitable for criminals. New activities have emerged as technology advances. Traditionally, consumers and businesses were lax with security as hackers could easily encrypt and infect any technological device. Hence, cybercriminal activities grew rampant in the global economy. Security protection, government involvement, and leading software companies have become strategic partners in combating cybercriminal activities. However, despite all these efforts, cybercrime is still growing. There are many strategic solutions to this growing epidemic, such as investing in anti-virus software and commonsense approaches to password protection. In order to reduce the amount of cybercriminal activity occurring globally, action needs to be taken immediately.

The targets are computers or anything device connected to the Internet, such as tablets or smart-phones (Sundarambal, Dhivya, & Anbalagan, 2010). Hackers affect the cybersecurity of large companies, government agencies and regular

customers, especially if competitive or personal information is stolen for ransom or extortion purposes. In the majority of incidents, it is relatively simple to trace back to the hacker, as many are nonprofessionals with little experience. However, it has become increasingly difficult to catch more sophisticated hackers. Although, if and when they are caught, there are significant penalties that come with hacking and computer fraud, many have argued that these penalties are not severe enough to deter such activities (Beldona & Tsatsoulis, 2010; Mohanty, et al., 2010; Smith, 2007). Some have suggested that such crimes are inevitable as IT systems become increasingly complex and globally interconnected (Dharni, 2014; Latha & Suganthi, 2015; Chand, et al., 2015; Han, et al., 2015; Soon, et al., 2015).

Exploring Types of Computer Fraud

To illustrate these trends, Stewart and Shear of SecureWorks™ have examined many hacker markets and found that cybercriminals are increasing their activity of stealing information (Clarke, 2013). Stewart is Dell's SecureWorks™ Director of Malware Research for the Counter Threat Unit (CTU) and independent researcher Shear have done much research into the dark marketplace that is frequented by cybercriminals. There are online tutorials for novice hackers to learn the trade for under US\$1. For example, one can access Social Security card numbers, name and address of customers for US\$250. Cy-

bercriminals can gain control of computers for US\$20 to 50. Customers can also hire someone to hack a website for US\$100 to 200. However, not everything is cheaper. The price of botnets, spam and malicious software, has increased from US\$90 to US\$600-1,000. Multiple sellers advertise “satisfaction guaranteed” on the data, which is designed to capture the attention of a potential or practicing hacker. It seems the traditional business model of value-added activities works well in the more hidden and illegal markets as well. However, organizations’ drives to understand and anticipate their customers’ needs ultimately forces management to connect valuable and vulnerable corporate systems to the general public and, thus, cyberthieves (Daim, Basoglu, & Tanoglu, 2010; Daramola, Oladipupo, & Musa, 2010; Dominic, Goh, Wong, & Chen, 2010; Kapur, Gupta, Jha, & Goyal, 2010; Keramati & Behmanesh, 2010).

Dell and its software SecureWorks™ are well-known and highly respected IT-security providers. Software and management at Dell has been investigating this illegal market for some time. Dell, as a provider of security systems, has in place this particular security software in over 61 countries with 4100 clients and has been providing top of the line service for the past 16 years. Dell SecureWorks™ provides a relatively quick warning to its clients when a cyber-attack is happening. It also provides a prediction of where the cyberattack is coming from and what it is trying to get from the computer. After the security system finds a cyberattack the system then works to get rid of it and tries to prevent the cyberattack from happening again. Counter Threat Platform (CTP) powers Dell SecureWorks™. CTP analyzes a total of 150 billion networks to find any possible threats, generate information, and find any information that could lead to a cyberattack (Alderete & Gutiérrez, 2014). Overall, CTP allows Dell’s SecureWorks™ to prevent, detect, respond, and predict.

Cybercrime an industry that has shown double digit growth year after year within the current struggling global economy. Cybercriminal activities have been on the rise and are becoming more

profit driven as its business model is evolving and new cybercriminal activities are emerging. Out of dozens of underground markets surveyed by SecureWorks™ researchers, a subsidiary that specializes in cybersecurity and data protection, it was found that business is booming. Not only have prices gone down on many of the services offered, but offerings have expanded as well. From basic hacking offerings to infecting networks of computers with the use of botnets, “underground hackers are monetizing every piece of data they can steal or buy and are continually adding services so other scammers can successfully carry out online and in-person fraud” (Lawrence, 2014). Cybercriminal activity has become a major global problem.

China, for example, tops the list for online crime hotspots with 83% of respondents residing there having been victimized (Bertolucci, 2016). According to the Norton Cybercrime Report (“Cybercrime Report,” 2011), 41% do not have an updated security software suite to protect their personal and online data in the U.S. Within this study, more than 65% have claimed that they have fallen victim to viruses and malware attacks, online scams, phishing, social network hacking, credit card fraud, and sexual predation. Many people are uneasy about the safety of online commerce, as they feel that the majority of online criminals operate within countries where prosecution is unlikely. Illegal downloads, digital piracy, and digital harassment are some of the other more common cybercriminal activities committed on a daily basis (Shinder, 2011).

Cybercrime is up 10.4% over the previous year as stated by Kassner (2016). In general, cybercrime has risen over US\$1.13 million domestically in the 2014 alone. Web-based attacks, denial of services, malicious insiders, viruses, worms, Trojans, malicious code, phishing and social engineering, malware, stolen devices, and botnets are among the top cybercriminal activities have cost the U.S. and other countries the most money in terms of lost productivity, cybertheft, and counterintelligence efforts. The actual price of cybercriminal

activities paid by hacker has decreased over the years. For example, the cost for a Remote Access Trojan (RAT) has dropped considerably in recent years, on part to the increased availability of free ones now available online (Lawrence, 2014). However, the price of botnets has increased from US\$600 to 1,000 for 5,000 of botnets within the U.S. With activities expanding and services more readily available, cybercrime is an ever-expanding industry and is on the rise.

Security protection, government involvement, and leading software companies have become competitive forces for cybercriminal activities. More security protection is being added towards platforms, PCs, mobile devices, and tablets. Security product vendors are also on the rise when it comes to cloud computing. As mentioned by Kassner (2016), cloud computing affords cybercriminals perfect opportunities. However, the use of cloud-based fraud detection can be used against cybercriminals. In general, applications of cloud services can pick up on patterns of criminal activity that would not otherwise be obvious with the collection and sharing of information from the millions of devices across the global economy.

Governments have also become a competitive force towards cybercrime. The U.S., as well as the U.K., has been investing heavily in their security infrastructures. The Department of Homeland Security within the U.S. is combating cybercrime by investigating a wide range of cybercrimes and conducting high-impact investigations to disrupt and defeat cybercriminals. The U.S. Secret Service maintains many electronic crimes task forces that are known to concentrate on identifying/locating global crime connected to cybercrime, bank fraud, data breaches, to name a few ("Combating cybercrime," 2016). The U.S. Immigration and Customs Enforcement, Homeland Security Investigations, and Cyber Crimes Center, are involved in cybercrime investigations by providing computer based technical services to support both domestic and international investigations in cross-border crime. The U.K. has recently spent over 63 million pounds in building

up its resources for fighting cybercrime. Large companies, such as Microsoft, have invested their resources in efforts aimed at tracking down and prosecuting cybercriminals. Microsoft, as well as other leading companies, has teamed up with NASA and the U.S. Department of Defense to develop international standards of making IT equipment far more secure than it is today. Despite the challenges presented towards cybercriminals as many cybercriminals having been prosecuted and their illicit organizations shut down, cybercrime is still on the rise and has soared 107% percent in 2015 (Watson, 2016).

Even though Dell is a leading IT-security service provider, there are several other companies that are close behind in terms of competitive offers ("SecureWorks competitors - CB insights," 2016). FireEye™ and Intellitactics™ are the two main competitors. FireEye™ provides its users with firewall, IPS, anti-virus, and gateway protections. These different types of security protocols are designed to protect the user's computer from many threats that may appear using day-to-day systems, such as e-mail and customer-service operations and normal e-commerce offerings. FireEye™ is a public service company that originated from and initial public offering (IPO). As an IPO, initial sales to the public after being released from a private company to a public company, specifically, FireEye™ is a provider that specializes in preventing cyberattacks, such as zero-day and advanced persistent threat (APT) attacks that bypass traditional defenses and compromise over many networks. Many zero-day attacks are purposefully designed to expose computer applications' vulnerabilities; hence there has been no time to develop a proper defense against such attacks. Unfortunately, many zero-day exploits are totally unexpected and frequently used by cybercriminals for malicious purposes. FireEye™ attempts to provide solutions that supplements signature-based firewalls, IPS, anti-virus, and gateways, and provides cross-enterprise, signature-less protection against cyberattacks and malware problems on clients' files.

To add to this misery, APTs utilizes many different phases and methods to compromise a computer network in order to avoid detection by anti-cyberthreat software in order to gain access to important information through thefts of information leaked out have relatively long time periods. Both FireEye™ and Intellitactics™ have specific safeguards against such attacks, but technology advancements always work to undermine such solutions.

Intellitactics™, such provides information security software for comprehensive enterprise security management, is a competitor in a different way than FireEye™. Intellitactics™ is part of the Trustwave® corporate initiative, which is a larger security business. Intellitactics™ is more of a pinpointed security solution. Intellitactics™ is more of a security information and event management system solution. This essentially means that the security system is more used by a business that stores important information on a computer or a business that stores planned events on a computer.

BACKGROUND

Businesses Affected by Hackers

Virtually every modern and web-connected business uses computer systems to keep track of its records and keep in contact with customers in order to make transactions smooth and relatively seamless. Unfortunately, these same systems also put a company at risk; not just the company that is affected it is also their clients (Aeron, Kumar, & Janakiraman, 2010; Barra, Savage, & Tsay, 2010). Firewalls and encryptions can be put into place and properly maintained, but if a determined hacker knows what he/she is targeting; undoubtedly, it is only a matter of time before these systems are eventually compromised unless significant steps and constant monitoring processes are implemented. Some of the major companies have been hacked recently (e.g., Sony, Home Depot, and Target) know this scenario too well. For example,

Sony Pictures Entertainment was made aware of the hack on November 24, 2014, but there is a possibility that the hacker had been in the system for almost a year (Fitz-Gerald, 2014). Names, addresses and social security numbers were exposed of over 47,000 current and former employees. Of course, as conspiracy theories develop, there was a theory that it was a current or former employee that was responsible for the hack and not terrorists' organizations as it had been originally speculated. Hence, as suggested by Barrett and Yadron (2016), companies and governmental agencies must be trusting partners in the war on cyberattacks and fighting computer hackers if such security breaches that was experienced by Sony in 2014 will become commonplace as warned by U.S. President Barack Obama stated in February 2016.

The industry position for individuals or companies that are illegally selling data on the Internet, unfortunately, still practices a number of traditionally practiced business models. These underground hacking markets are constantly changing with the new technology that is allowing for cheaper options, which makes it easier for hackers to access customers' computers. For an example, one year the black market price for a RAT could be up to US\$250, and then the next year it could be down to US\$20 ("Underground Hacking Markets Report," 2014). Such inconsistent markets puts pressure on the hackers not knowing if this data will be high or low on black market, which forces hackers to innovate and more dangerous ways to infect computers on a global scale. Unfortunately, what may be at risk can be both intellectual property and personally identifiable information (PII) that ties information directly to an individual company and/or customer (Shukai, Chaudhari, & Dash, 2010).

In terms of state-sponsored cyberterrorism, North Korea is typically blamed for many widespread cyberattacks, regardless of proof of their true degree of involvement. This is part to its suspected involvement in preventing a movie, *The Interview*, from being formally released. The film, about assassination of the President of North Korea, the hackers, identifying as "The

Guardians of Peace,” tried to prevent its release through public discourse. The hackers did not leak everything at once but slowly and information is still being released to this day. The hackers promised they would stop the leaks if Sony cancelled *The Interview*’s theatrical release. Personal e-mails between company employees and actors were released, as well as confidential salaries of celebrities and top employees. Despite this pledge, significant and personally damaging information was getting released daily. Management at Sony went ahead with the movie’s release, but instead in theaters, customers could buy the movie at home because movie theaters were getting threatened if they aired the movie. It was in December, 2014, that the FBI stated that North Korea appear to be involved although the government of North Korea officially denies it and threatened the White House and pentagon if the U.S. government levies any punishments. Following the Sony hack, other studio companies took precautions and cancelled their own North Korea-themed movies. Currently, Russia is accused of interfering with the 2016 U.S. presidential elections.

Another well-publicized major incident of a company that was targeted by hackers was Target. A few days before Thanksgiving, 2014 a malware was installed on Target’s security and payment systems at POS, so that every time a customer’s card was swiped it would take the card number and store it in a separate system for the hacker to retrieve at a later date, possibly suggesting insider involvement (Riley, Elgin, Lawrence, & Matlack, 2014). On “Black Friday,” when many customers do their Christmas shopping, over 40 million customer accounts were breached. In the aftermath, over 90 lawsuits have been filed against Target from customers and bank for negligence. In March 2015, a federal judge approved an offer of 10 million from Target to settle a class action lawsuit if the customers affected can actually prove they were affected since banks usually reimburse 100% for card fraud (Riley & Pagliery, 2015).

These documented breaches on global companies that traditionally make significant profits

have spent considerable financial and human resources cybersecurity on their data and networks that support them. Obviously, such investments do not guarantee protection (Kim & Tadisina, 2010; Marthandan & Tang, 2010). But how do the small businesses successfully protect their customers’ information? Based on prior studies, over 90% of small businesses in the U.S. do not use data protection for their business or their customer’s information and, hence, this is costing business and their customers’ considerable financial and other resources (Warren, 2015). A small business can start off by making sure their employees are not visiting the wrong kind of websites and getting cybersecurity insurance. Retail and finance business are at higher risk than restaurants but they are still considered a target.

From a strategic perspective on the nature of cybercrime, the competitive forces for a company illegally selling data on the Internet are unique (Smith, 2007). The availability of automatic identification and data capture technologies (AIDC) and its relatively low cost have helped to develop the underground cybercrime industry. The cybercrime industry varies widely on the enforcement of government regulations and legality of the information exchanged (Jarrett, 2016). The barriers-to-entry are low, as anyone with enough knowledge to gain the valued information can become a seller; therefore, the threat of new entrants is high (Elysee, 2015). Buyers have a high degree of bargaining power, as there are nearly endless sources of this information available on the Web and in person. Since customer service is important in the industry, as there are many sellers and there is a need to differentiate their services. Sellers have a relatively high degree of bargaining power as well, since there is little enforcement of laws around the sale. For example, if a seller sells a “bad” ID that does not work, the buyer has little means of getting its money back and will likely not use the law to enforce a botched sale or contract.

A number of authors (Aeron, et al., 2010; Barra, et al., 2010; Shukai, et al., 2010) have discussed the available and effective security defenses that

have been developed and continue to grow in effectiveness for all of the security threats mentioned. No security defense can be completely effective, but many of these can be used to help avoid major breaches, known threats, ordinary hackers, and security ignorance. Perhaps the most obvious defense is the personal firewall, which provides antivirus and anti-spyware. Firewalls help devices by blocking or limiting the use of Bluetooth and Wi-Fi unless asked to connect. This is difficult to ensure that every device follow because many devices encourage the user to allow connection to Bluetooth for all types of traffic. Antivirus and antispyware scan network traffic for signatures of known malware. These types of mobile security are not widely used on mobile devices but will become more available due to the target malware has on the devices as technology progresses. As suggested by Friedman and Hoffman (2008), there are limitations of firewalls, antivirus and anti-spyware, that are based on their inability to block malware that goes through the port that is in use. Also, virus writers and cyber criminals have found ways to evade signature based antivirus and antispyware by using short-span attacks and designer malware. Because of this additional defenses are available as a sort of back up to the backup protection. Intrusion prevention systems examine network traffic into and out of the computers and identify sketchy behavior. This form of protection establishes a baseline of normal online behavior and is alerted when there is a significant change.

For the defense against phishing and social engineering, education may be the best defense. This includes being informed on what accurate looking e-mail appears from their banks or institutions, what phishing messages, what unknown websites may appear based on URL observing and just the knowledge that giving out personal information to someone online. Content and spam filtering are known best for maintaining a large list of known websites that are known for spamming or housing malware and it in many ways blacklists them and blocks them from incoming. Other

ways of preventing communication interception and spoofing can be accomplished by disabling unneeded communication, password encryption, virtual private networks, and to restrict access to hot spots. A user can disable these unneeded communication methods and ports by changing configuration settings on the system being used and avoid hackers from unknowingly obtaining information without the device users consent. Good password encryption will help the device carrier to use algorithms in order to protect the device and applications the user may have important information on as well.

Defense against loss and theft of devices are better known as many users already use locks on their devices to keep only them from accessing their device. Some devices have “time-bomb” capability, so if the device is lost or stolen and someone tries to obtain information from it, it will wipe it and destroy data on the device. Many devices also have back up or a recovery mode, which replaces lost or stolen files. Device control can be used to prevent files from being written to USB and requires that files be encrypted. By encrypting files, regardless of a loss or theft, files can remain confidential and are less likely to be leaked to outside sources.

CONCLUSION

Legal Solutions Are Inadequate

In conclusion, fraud is a crime that will always be relevant and present, even as the technology to protect against it grows and strengthens. Laws and regulations put in place to prohibit such actions can only do so much in combating against such threats. Many cases arise from fraudulent activities and will vary in degree of damage, but with each case is the degree of the crime, unique to the case. For every business that uses computer systems, managers must become beware of threats with the hope of a better functioning system and a rise in profit. Strategic recommendations for

security providers vary depending on the type of security you provide. For companies, like Intelitactics™, it is to provide reassurance that their customer's information will be kept safe from the unauthorized public. To do this properly, they market protective measures to ensure that hackers cannot get into stored information. For companies, like SecureWorks™ and FireEye™, where customers are working more with individuals than other businesses, it is equally important to gain their trust by providing successful documentation and cases. It is important to keep customers in constant contact and insure that if a problem is detected that they will be alerted immediately. Keeping customers updated on the innovative hacker technologies would gain customer trust by keeping them in the information loop and alert.

It is important to raise the awareness of the potential punishment for those who may think of illegally purchasing a product or service from hackers and look for a strategic alliance where they can work with another company or companies to raise the defenses against hackers. Specifically, in the late 2015, Lifetime, Netflix, Pandora, and Hulu accounts were being hacked and sold online for as low as US\$1. For the average consumer with little technical background information, it seems like a great purchase bargain, but since these accounts are stolen, there are consequences to the consumer if they are found with such account. With the proper investment into the awareness by Internet users, hackers would have no market or interest to sell stolen accounts. If such companies as SecureWorks™ were to partner with each other to raise account security standards, these accounts would be much more challenging to hackers, as they typically go after soft targets. Ultimately, as evident from the researchers cited in this chapter, a major threat to the global economy is the general lack of Internet security. With advocates for stronger defense systems like those, there should be a stronger movement towards more secure networks and acts at tracking down sites used to sell hacked goods. In essence, there was a variety of information presented in this chapter regarding

how the reader could arm himself/herself in the probability of an attack by a hacker through better education of the nature of cyberattacks.

Strategic Implications

In order to attempt to catch up to this growing epidemic, fast and decisive actions are required. Even though mobile phones and smart devices have remained relatively safe, users are vulnerable targets, as presented in the 2011 Norton Cybercrime Report. Consumers have to become more protected by installing security programs not only on their PCs, but on their mobile devices and tablets as well. Every year it is getting easier to hack computers and counterfeit items such as passports. It is also becoming more “mainstream” in the e-marketplace. The cost to hack websites, for example, has fallen 33% in the last year alone. It has become easier to be a hacker or hire a hacker than it would be to invest in advanced security protection software. In a matter of years hacking will become as easy as going to a drug-store if it is not stopped soon.

The continuous demand and growth of cybercrime has led to the development of a new industry to offset its negative impact; cybersecurity. Corporations and individuals can protect their electronic gadgets by installing anti-virus programs and file restrictions that blocks access as well as detecting and eliminating malicious ware before it expands. Anti-virus software is the most common solution to combat lower degree of cybercrime activity such as Trojans and worms. Another strategic measure that can be taken is to pay close attention to the source of e-mails and their content; if the information seems unfamiliar or the sender is unknown, the receiver should eliminate the e-mail without opening any attachment or providing any information.

Besides computer infiltration, spam and phishing, another common form of cybercrime is identity theft. This criminal activity is possible due to the amount of information that is stored in computers, social media, employment forms and

e-mails. The easiest way for criminals to obtain personal information is through social media, therefore it is better if accounts on websites such as Facebook or MySpace are accessible by friends only, and all pictures that contain addresses or telephone numbers are blurred or removed. While it might seem innocent to fill out personality tests and surveys, it is better to investigate the source of these; Facebook, for example, allows independent developers to create customized applications without verifying their identity and intentions. In many cases, identity theft can be extremely difficult to detect in the beginning since criminals tend to keep a low profile. An obvious way to fight this can be by monitoring accounts and financial information on a constant basis and to report all suspicious activity to the law enforcement activities. Companies such as Discover notify customers of transactions that takes place a specified distance from a set location, and Chase Bank, for example, asks for verification codes every time a new smartphone or computer is used for a balance inquiry.

Commonsense approaches include never use the same password for more than one account as well as the use of common information for security questions. Much of cybercrime can be stopped in the effective use of passwords and 2-step verification methods, using access codes that are texted or sent via voice mail. Social media and acquaintances may provide enough information to third parties unintentionally and might allow access to bank accounts, retirement funds, e-mails and other accounts. It is highly suggested to elaborate passwords that contain numbers, different characters and unrelated dates and names. These measures can help fight cybercrime since there is no better solution than restricting the amount of information to which someone has access.

In conclusion, to fight cybercrime it is necessary to constantly monitor accounts that involve trading or savings for any suspicious activity, observe the sources of suspicious e-mails and avoid opening files or filling formats that seem illegitimate. Restrict privacy settings in social

media networks and destroy physical evidence of important information, such as old utility bills or any addresses from envelopes, birthday dates, etc. If completing purchases online, using trusted sources like PayPal®; if that option is not available, use prepaid gift cards to keep bank or credit card account information safe. Installing and maintaining an anti-virus program can help prevent possible malware from infecting the user's computer. The use of different passwords and security questions for each account can also aide in the protection of being hacked. Companies and countries that have gone beyond the current standard security protocol have achieved great results in the prevention of cybercriminal activities.

FUTURE RESEARCH DIRECTIONS

Much of the information presented in this chapter typically applies to many daily business situations. They are particularly relevant in the era of big data analytics and the growth of identity theft, evident to the widespread nature of malicious attacks. The increasing likelihood of being a victim of cyberhacking is well documented by academics and practitioners alike. Fortunately, essentially every cyberthreat has a potential solution that is attainable by consumers seeking prevention, but the legal professional and governmental action leaves much to be desired in dealing with these threats.

Ultimately, perhaps the best advice when customers and organizations are confronted with these threats is the need to promote education and commonsense prevention. Cybercriminals will always seek soft targets, generally caused by lack of easy prevention techniques that could easily be prevented if proper education is made more universal. Further research needs to deals with this problem of making such educational opportunities more available and easy-to-use. The particular needs of each individual in regards to defense in dealing with the various ways they could be attacked must be addressed. If organizations can use big data analytics to e-personalize their products and services; why not apply the same

technologies to customize defense and safeguards against cyberattacks? For example, when it comes to phishing, of which there are countless victims, with the proper education they can learn to detect what is fraudulent and withhold their information from getting out to these cybercriminals. Hence, essentially every attack is preventable regardless of whether it is a phishing scheme, malware attack, data communication interception, loss or theft of device internal breach, and/or a virus attack. Future research that is aimed at educating potential victims would provide much relief in these ever increasing cybercriminal problems. The authors of this chapter suggest that further research should continue on all levels of cyberattacks. Society, in general, is becoming more vulnerable to such attacks and educating customers and managers about different threats and opportunities made available to counter hackers that are becoming more intelligent on ways to undermine the various precautions put in place, makes the needs to make potential victims more intelligent about cyberthreats even more pressing.

KEY TERMS AND DEFINITIONS

Advanced Persistent Threats (APT): Advanced Persistent Threats typically employs a number of phases and techniques to break into a network, avoid detection, and gather customers' or companies' information over an extended time period. Unfortunately, such well-planned and extensive strategy is difficult to detect, as it many techniques and phases may be extremely complex and expensive to develop a counteroffensive that is successful.

Direct Cyberattack: Direct cyberattack causes data communications interception at the hands of a specific hacker who may have located a specific person or Wi-Fi area in order to perform such cybercrime. A type of direct attach is direct access, where the criminal gains physical access to either the computer or its network in order to compromise security by loading worms, Trojans, compromising data, etc.

Personally Identifiable Information (PII): Personally identifiable information (PII) refers to all information, including personal financial and healthcare information that can be traced to an individual customer or patient.

Remote Access Trojan (RAT): In basic terms, Remote Access Trojans (RATs) are essential tools available to cyberthieves with unrestricted limited access to computers. By using stolen access privileges through properly submitted passwords, all important business and personal data, the entire customer's or company's information can be readily accessed and retrieved.

Zero-Day Attack: This term has been used in various forms and meaning. It terms of this chapter, this term refers to exploitable software or hardware vulnerabilities that have been attacked when there has been no previous information of a system flaw by the general information security community. In such a situation, unfortunately, there is no vendor fix or software security patch that have been developed or made available to the public to correct or protect against such an attack.

Cost Estimation and Security Investment of Security Projects

INTRODUCTION

Project management is an important task that should be performed when dealing with security project, since it allows avoiding different project failures. This task is an effective methodical approach of planning, organizing, leading, and controlling resources to achieve organization's goals. It involves, thus, identifying requirements, determining clear objectives, and balancing the triple constraints scope, time, and cost (Institute, 2013).

It is noted that the management of software and security projects are not performed in the same way, due to several reasons, related mainly to the software intangibility, complexity, conformity, and flexibility. It is also shown that the parameters involved in the security cost estimation differ from those of software cost estimation. Therefore, the developed methods should be adapted to consider security specificities.

In this context, organization's project managers should estimate the cost associated to a security project during its design. This estimation should include the computation of the optimal security level and residual risk accepted by the organization. Moreover, it should consider managerial aspects regarding, for example, the effort required for security monitoring of the new assets to be acquired or updated, the security training of the technical staff, the update of the managerial deci-

sional system, and the development of policy and procedures related to the use of information processing facilities, instead of only considering the industrial source coding of the security packages.

Another significant aspect, which should be carefully examined when dealing with security, is related to security investment. The financial budget allocated to security should be well established and managed to avoid under or over expenses. Different security investment models are developed in the literature using various techniques and examining several features. Most of them have focused on determining the optimal security investment allocation based on budgetary aspect, economic, and financial constraints. Recent works are interested to examine more specific security features when assessing the required investment, such as the system vulnerabilities, attacks type, risk factors, data privacy, and insurance.

This chapter aims at examining two aspects related to security project: cost estimation and investment assessment. First, the characteristics of security projects are stressed on and the importance of adopting management is determined. Then, the chapter presents the different cost estimation models dedicated to security project and discusses the technical and managerial factors affecting the cost estimation and the management of project. In addition, a sample review of research works directed toward security investment models is determined. These models are organized according

to the type of issues and aspects handled to compute the optimal amount of security investment. Finally, the chapter discusses future directions that could be investigated to make available useful models for cost estimation and investment on security projects.

SECURITY PROJECTS MANAGEMENT FRAMEWORKS

In this section, we examine the objective and features of security project and show the importance of the management task when dealing with these projects.

Definition and Characteristics

Security project is a specific type of project that implements a set of tasks to protect and secure a considered information system from attacks and potential threats. It lies usually outside the core functions of the business and aims to protect critical involved resources.

Security project is different from a software project for at least five features which characterize it:

- First, the security project requires a better knowledge of the security threats and vulnerabilities surrounding the activity of the enterprise, their future severity, and the evolving techniques they will implement. In addition, managing efficiently a security project assumes that the remaining risk related to damaging attacks, unobserved during project design, will be confined in the future. Moreover, the necessity to provide a response to significant attacks supposes that an efficient monitoring of activity and risk assessment are guaranteed.
- Second, the output of security projects is complicated and may include: (1) a security policy customized to the enterprise, its activity, and its environment describing the rules to be enforced, the security Procedures to be observed, the detection to perform, and the security invariants to comply with. While a security policy acts as a specification of the security project, it differs from a specification in the way it involves the activity of an incident response team and the procedures it triggers on the occurrence of attacks; (2) a set of preventive, detective, and responsive systems to be deployed in a way that allows flexible configuration and real time connectivity to other information and decision systems in the enterprise; and (3) a set of countermeasures to introduce on preventive and monitoring tools to thwart future attacks along with security procedures and guidelines to be followed by people when immediate reactivity on the managerial procedures is needed.
- Third, estimating security project complexity is influenced by different factors, such as the size of the information system to secure in terms of number and size of interconnected sub-networks; the number of users exploiting the information system resources including customer users connecting remotely and administrators; and the complexity of the security policy defining the measures to implement and rules to enforce.
- Fourth, a great part of the work in a security project is added on the customer network in order to: (i) interview the users, security administrators, and managers, especially during the risk analysis phase to identify the managerial issues that can affect the project; (ii) integrate and configure the developed solution and update the existing networking solutions to guarantee an adequate inter-operation; and (iii) assess the robustness of the resulting security system through auditing and penetration testing.
- Fifth, a security project has to keep under control the variation of the security robust-

ness of the project over time. This need is difficult to achieve since vulnerability models cannot handle a good perception of the vulnerability evolution.

Management Role in Security Project

Security project, as all types of projects, needs a project management activity in order to better pursue its objective. Indeed, this latter is considered as a process that helps producing successful projects by ensuring that the key elements of the projects are included in the right order at the right time.

A successful security project requires a good management of ten key elements (Stahl, 2008): (1) project scope, (2) project time and schedule, (3) project cost and budget, (4) project resources (internal and external), (5) contract management, (6) procurement management, (7) project communications, (8) quality management, (9) project risk, and (10) cross-organizational coordination.

The project management activity consists in organizing, planning, and scheduling tasks. These later represent the most time-consuming project management activities. Therefore, elaborating and following a security project plan is a useful way before implementing security solutions. The developed security plan will be customized to fit the type and the needs of the organization to protect. The major steps include identifying threats, analyzing and prioritizing threats, developing plans and strategies to reduce the occurrence likelihood of the identified threats, and elaborating contingency plans.

It is noted that various benefits are determined when adopting project management to security project. In fact, the core advantage of performing the management is to avoid some projects failures, related for example to over estimation of the budget allocated to security project, unrealistic timelines for the different security tasks achievement, and large definition of the project scope. Moreover, adopting project management provides a strong framework for roles and responsibilities. This is crucial since the role of security is often misun-

derstood by many within an organization. A highly defined role for security can help alleviate friction between the security program and the rest of the organization (Gentil, 2015). In addition, the management allows defining for each process group of the project (i.e. initiation, planning, execution, controlling, and closing) the set of issues to be solved as it is specific for each group.

COST ESTIMATION MODELS FOR SECURITY PROJECTS

This section provides a brief survey of the developed cost estimation models for security projects. It also highlights the importance of integrating technical and managerial factors in these cost estimation models.

Review of Existing Cost Estimation Models

The developed cost estimation models for security projects are not as popular as those dedicated to software projects (Boehm, 2000). The ones described in the literature are cited in the following.

Labor Time Estimation Model (LTEM)

The model is described in (Sato, 2009) to estimate the labor time of information security audit projects through the estimation of the labor time of its four phases, i.e., planning, implementation, reporting, and improvement. The estimation is based on factors related mainly to the type of the audit form, the operation mode, the enterprise size, and the penetration degree of information security management. These parameters are measured through performing quantitative and regression analysis of data collected from past audit projects.

Despite the suitability of the LTEM model to assess security audit projects, it is noted that it is not appropriate to estimate the cost of security projects due to a number of limitations. In fact, the model considers few parameters which affect the

effort and the cost of conducting security projects. Factors related to the information system to be audited or reporting on the auditing team skills could be considered. In addition, the applied size estimation technique is only based on the number of employees involved in the audit process, and does not consider the information system components that could affect it. Another important limitation of this model lies in its lack of consideration of the security policy, which could be used as a baseline for auditing, analysis, compliance checking of the information system, and the correctness of the configuration of the security solutions to the security rules. Therefore, the security policy could introduce additional labor time on the audit activity, especially, when inconsistency is noticed. Furthermore, a security policy can be used in size estimation as it provides more constraints than a specification.

A Security Cost Model (SECOMO)

This model aims at estimating the effort required to conduct a security project (Krichene, 2003). It provides a basis for determining how much time, cost, and personnel are required for security projects. It is founded similarly to the Constructive Cost Model (COCOMO), which is a hybrid cost estimation model based on regression and expertise based techniques.

SECOMO defines three security cost models, classified into basic, intermediate, and advanced. These models differ according to their complexity, size, and the strength of the security policy they implement. In addition, they are based on the size of the network to be secured and use a set of cost drivers, decomposed in effort multipliers and scale factors, that give a measure of the security task complexity and where their effects are different. Effort multipliers have linear effect on the estimation, whereas, scale factors have an exponential impact.

Despite the contribution of this model to the management of security projects, some limitations could be identified. First, SECOMO is tailored to

enterprises developing security software. It cannot be used, as it is, by any enterprise assessing the total cost of a security project it wants to acquire for itself. Different used parameters could not be estimated accurately, such as developing team capability and tool experience since they are intrinsic to a software development company. The second limit is related to the inability of SECOMO to consider the managerial effort related to the integration of the solutions to systems dealing with strategic intelligence and the organizational security documents. In fact, a large set of managerial and organizational tasks within the enterprise should be accounted during the cost estimation as they are included in the enterprise's security policy. In particular, the awareness activity following the deployment of a security solution is not considered in SECOMO.

A Managerial Issues-Aware Cost Estimation of Enterprise Security Projects (MCE)

The MCE cost estimation model is an extension of SECOMO and COCOMO models. It is developed to conduct a security project and integrates the impact of managerial and technical aspects related to five types of tasks, namely monitoring, awareness, decision making, re-engineering, and integration and compliance (Fessi, 2013). The developed model allows managers predicting the cost associated to a security solution according to the enterprise's needs, and thus they (i.e. managers) could define and manage efficiently their project budget.

The developed cost model depends on the size of the information system, the size of the existing security policy (SP), the enterprise size, in addition to a set of cost drivers. It allows estimating numerically the managerial impact on the cost associated to a security project, compared with the other existing models. Moreover, it gives an important role to the security policy supporting the security project, as it represents a key element for estimating the required effort and the expected cost.

It is noted that behind the provided benefits, the developed model is closely tied to the content of security policy (SP), which is considered as a static document during the project estimation time. In reality, SP must be adapted to the environment where the enterprises operate. This latter is characterized by its complexity and uncertainty where threats and vulnerabilities increase continuously, attackers change their behavior over time, and resources may show dynamic features. Moreover, MCE lacks of tools for the estimation of the financial cost associated to the residual risk which is not addressed by security project. In fact, by considering the risk value, the enterprise could take the appropriate decisions to invest or not in the security project. We notice that this limitation is shared with the other developed cost estimation models.

Technical and Managerial Factors Support

The presented security project cost estimation models (Krichene, 2003; Fessi, 2013; Satoh, 2009) show the involvement of two types of factors: technical and managerial. The first set of factors are those related to the enterprise assets and to the security solution, whereas the second set is associated to the enterprise management features, such as organizational, human, and risk management. This integration of managerial factors besides technical ones into the estimation of the cost of the security project allows more accuracy to determine security budget allocation.

As it is mentioned beforehand, several factors are identified in the presented models. For the LTEM model, factors that influence the labor times include the type of business, the audit form, the operation mode, the penetration degree of information security management, and the enterprise size. For the SECOMO model, 23 parameters are defined and referred to as effort multipliers factors (i.e., product, personal, project, and information system) and scale factors

(i.e., precedentedness, team cohesion, project maturity, and security strategy). And for the MCE model, 19 parameters are identified and are allocated according to their relation to information system size, security policy, enterprise size and the defined five tasks (monitoring, awareness, decision making, re-engineering, and integration and compliance). Despite this variation of parameters between the presented models, it is noticed that some parameters are considered in two or all models, but have different designations such as audit form parameter in LTEM and audit frequency parameter in SECOMO; the enterprise size parameter presented in LTEM model corresponds to multi-site information system parameter in SECOMO model and it is also used as a key measure in the MCE model.

The different cost drivers could be assessed either quantitatively or qualitatively. Quantitative measures are determined on the basis of historical data, defined functions, statistical measures, or even experts opinion. Qualitative measures, in the other hand, require the intervention of experts to define the scale level of each parameter, and then approximate measure could be affected to it. For example, in SECOMO, the whole majority of parameters related to personal, are qualitative parameters, while in MCE model, strategic intelligence and awareness factors are qualitative and should be determined by experts.

SECURITY INVESTMENT MODELS FOR SECURITY PROJECTS

Several research works are developed to compute the optimal amount of security investment from the financial and economic perspectives. Recent works are directed toward integrating new aspects related mainly to cyber-insurance, security vulnerabilities patching, and game theory in cybersecurity investment. These models are described in the following paragraphs.

Economics of Security Investment Models

Determining the optimal amount of security investment which minimizes the risk of security attack is still an open issue for decision-makers, due to several factors such as the limited financial budget allocated to security information systems, the near-impossibility of eliminating security residual risk, and the dynamic and evolutionary aspect of different types of vulnerabilities and threats facing the firm's information systems.

Several works have been developed to handle security investment problem using a multitude of economic and financial approaches and techniques, such as risk-return analysis (Hausken, 2014; Gordon, 2002), utility theory (Huang, 2013; Miaoui, 2015a), game theory (Cavusoglu, 2008; Hua, 2011) and real options theory (Li, 2007; Tatum, 2009; Ullrich, 2013). The security optimal investment model based on the maximization of expected net benefits was first proposed in (Gordon, 2002). In this model, the decision-makers, which are assumed to be risk-neutral, maximize their expected incomes from security investment by comparing the marginal financial benefits and the marginal financial costs of information security. The model analyzes the impact of several parameters, such as system's vulnerabilities and potential financial loss on the amount of optimal security investment considering two classes of security breaches, namely targeted attacks and distributed attacks.

In (Huang, 2008), utility based model is used to determine the optimal security investment with the assumption of risk averse decision-makers. Considering each class of security breach probability, as assumed in (Gordon, 2002), different scenarios are conducted to analyze the relationships between optimal security investment levels and the potential loss, the extent of the decision maker's risk aversion, and the investment effectiveness. In an extension work, the authors developed an analytic model that optimizes the allocation of security investment to defend against concurrent

heterogeneous attacks on a firm's information systems (Huang, 2013). The model considers the budget constraint that all firms face and is based on the concept of scale-free networks to obtain breach probabilities for different classes of attacks.

Another context of security investment is examined in (Miaoui, 2015b), where the firms outsource or offshore their business operations. In this case, particular aspects related to bilateral security risk and data privacy are considered when computing their security investments. The developed model considers the involvement and interdependency of several stakeholders (e.g., attackers, the privacy protection firms, data sellers, and outsourcing companies) in conducting and protecting against privacy attacks in the context of an outsourced business activity. Moreover, the authors designed different models related to security threats on data privacy and consider the particular aspects of privacy attacks when determining the expected monetary loss and benefits. They also conducted a numerical analysis to assess the impact of the quality of detection and reaction to privacy breaches on the amount of optimal investment and residual risk.

Cyber-Insurance Investment

Several investments can be adopted by companies to protect their information systems against damaging security incidents, such as self-protection, self-insurance and cyber-insurance. The self-protection investment includes the development of security policy, the design of architectures and the deployment of security solutions (including, but not limited to anti-virus, firewalls or intrusion detection mechanisms) to mitigate the occurrence of security breaches, while the self-insurance investment is an internal investment made by an enterprise to cover himself from a financial potential loss. To reduce the large amount of potential losses induced by cyber-attackers, an investment in cyber-insurance can be undertaken by an enterprise (insured) to transfer the financial risk of security breaches to a third party partner (insurer).

An insurance contract is, thus, established between the two parties (insurer and insured) including in particular, the insurance premium to be paid by the insured firm and the reimbursement rate at which the insurance company will cover the amount of potential loss.

While the transfer of risk through an insurance company was suggested, by practitioners and academics, to cover the expenses and losses induced by security breaches (cost of notification and response to security incidents, loss or corruption of data), complete the existing set of security countermeasures and manage the security residual risk (after investments in cyber-security have already been made), the growing evolution of cyber risk and the interdependency of information security risks (due to interconnections of computers across different firms) have made the cyber insurance investment particularly complex, unclear, and more challenging (Zhao, 2013).

Indeed, as a classic insurance, the cyber-insurance raises several issues related to: a) pricing which is the amount of premium to charge to the insured firm in turn of potential loss coverage. To determine the appropriate price, insurance company should accurately estimate the cyber risk incurred by the insured firm. However, some estimation bias can be introduced when the applicant firms have high risk interdependencies due to their high information systems openness to external environment and/or their degree of information sharing through outsourcing operations; b) adverse selection which is a hidden action problem arises when the insured firm does not communicate its real security risk in order to benefit from lower risk premium. To deal with this problem, the insurance company can estimate the security risk of the applicant's resources, the systems vulnerabilities and the threats through security audit. As the security vulnerabilities and threats severity, frequency and evolution with respect to time are increasing, security incidents occurrence probability as well as the potential loss

to be reimbursed by insurer are also increasing; and c) moral hazard which is an asymmetric information problem arising from the non-ability of the insurance company to observe the behavior of insured firm after purchasing cyber-insurance. The latter may behave recklessly in order to increase the likelihood of insurance claims.

In fact, although an insurance contract does not prevent security breaches from occurring, some firms may find it cost sensitive to invest in cyber insurance than in self-protection. In the worst case, untrusted insured firms could create fictive self-attacks and ripe benefits from the insurance company. Therefore, a high premium or a low coverage (e.g., use of deductibles) should be given to firms that do not take the appropriate measures to reduce the probability of loss, or that are unable to prove that the incident is not self-generated.

In this context, several models were developed to cope with these issues (Gordon, 2003; Herath, 2011; Böhme, 2010). In particular, cyber insurance has been proposed as a promising solution to manage security risks and to optimize security investment. In (Ogut, 2005) and (Bolat, 2008), the impact of cyber-insurance investment is studied, when firms face correlated risk on the cost and efficiency of security investments, and on the increase of incentives to invest in self-protection. In (Grossklags, 2008), a model of security investments interactions using game theory was proposed. The authors show how the players decide strategically to shift between investment in self-protection and investment in cyber insurance. Recent work proposed by (Miaoui, 2015a) is focused on the importance of security investment in forensic investigation to collect digital evidence and generate provable insurance claims to ensure a better reimbursement of loss in case of security breaches occurrence. The developed investment model is based on three interdependent investment types: investment in self-defense, investment in insurance, and investment in forensic readiness.

Security Vulnerabilities Patching Investment

The detection and the patching of vulnerabilities represent important tasks that keep an information system secure. Security administrators should typically proceed as soon as possible with the application of patches or the modification of security policy rules (e.g., deactivation of vulnerable services, ports filtering) to prevent potential exploitation of the identified vulnerabilities. In practice, different reasons may delay or prevent a firm from the immediate application of security patches, such as: (1) the number of patches to be deployed is important and their implications on security vary accordingly so that it is necessary to sort and prioritize vulnerabilities, which is a labour-intensive task; (2) there may be many available fixes for an identified vulnerability (i.e., official ones released by the vendor, and other ones released by the security community experts), so a test of compliance with existing software should be performed; and (3) a maintenance period, where the production system needs to be rebooted or temporary disconnected, could introduce an economic loss if it is required.

This delayed application of patches could lead to serious economic losses and could have severe security consequences. Therefore, a firm should design a patch management strategy to determine the time and the appropriate patch to deploy for the detected vulnerability. This strategy will keep the safety of the system, reduce the operational cost, and reduce the security risk of loss to an acceptable level. In this context, some research works are directed toward this issue and propose economic models based on game theoretic approaches to derive the optimal strategy and frequency of patches update. This strategy depends on the operation cost model, the required downtime period, the patch release policy of the software provider, and the stochastic vulnerability release. The developed model in (Cavusoglu, 2006) defines an objective function to minimize the damage cost of exploiting an unpatched vulnerability and the update patch

to shield vulnerability at the client company. This latter is assumed to incur attacks either because it is waiting for the release of a patch or because the patch is released but it is waiting the end of the update cycle. For the customer firm, the software vendor firm is assumed to release vulnerability fixes every predefined period of time, incurring consequently two different losses: patch development and release losses, and reputation cost.

Game Theory in Security Investments

Regarding the previous approaches, where the security investment is considered as an optimization problem that determines the best compromise between the security budget to spend and the residual risk to accept, several recent works are interested to use the game theory as a security tool to model the cyber environment under which defenders and offenders interact together. Such a theory will capture the behaviour of the attacker which varies depending on the strategy of the enterprise in defending and responding to security attacks. In most real scenarios of cyber protection, several actors interact together, including insurance companies, privacy protection firms, defender, third party companies, network and security providers, and even security authorities. All of these actors try to improve their expected benefits and therefore they adapt their behaviour to the visible or hidden properties of the cyber environment (available resources, loss of incur, identification ability, etc.).

In the context of security economics, several applications of game theory were proposed during the last years. In (Nagurney, 2015), information asymmetry between sellers and buyers is introduced to determine the optimal security investment at the seller side. In fact, contrarily to sellers which have a good knowledge of their security investment and the residual security risk they incur, and want to maximize their expected benefit from selling their products on the Internet market space (and therefore execute

secure transactions); buyers set their preference regarding the product prices based on the average provided security level of the seller (this security level is imprecise due to information asymmetry and is not related to individual sellers, but simply reflects the average security level in the industry). The used game theory determines the Nash equilibrium by which sellers can assess the cyber security investment, the expected damages in case of attacks, and the attacks probabilities.

In (Panaousis, 2014), the game theory is used as a tool to model the cyber security environment of a firm, as well as a non cooperative control game between a defender and an attacker. The former abstracts decision makers in security to protect the firm's assets and the latter abstracts all untrusted parties that aim to compromise the firm's assets. In this work, a security control is defined by the firm with respect to the direct and indirect damages that it can avoid on all targets. The game is modelled based on a two player minimax game, to allow defining one security control to implement, by which the more the attacker gains, the higher will be the firm's loss. Moreover, the proposed model implements a multi-objective optimization problem to derive the optimal allocation of the security budget, since different security controls are required by the firm to defend against the different security vulnerabilities.

Another model is developed based on the game theory approach (Fielder, 2014) to support making decisions regarding the allocation of security resources, including the time consumed by administrators in security their systems. The proposed model assumes that an attacker could harm many targets, and each target is threatened using a single vulnerability. Therefore, to defend against attacks, two security levels are considered, namely baseline and best practice. The former describes the probability of an attack, while the latter denotes the percentages of attacks being defended.

FUTURE RESEARCH DIRECTIONS

This section presents a number of future research directions related to unsolved challenging issues by the current cost estimation models of security projects. It also examines new research trends expected to determine an optimal security investment model.

Cost Estimation Models

To enhance the cost estimation of security projects, a set of consideration should be involved in the computation task. The first concern is related to the management of uncertainty and dynamicity related to the environment where the solution will be deployed. In fact, the cost estimation model should be extended to include additional factors that manage this uncertainty and cope with the variation of the protected environment by the security solution. It is, therefore, important to develop proactive cost models that tolerate modifications on the security policy during the achievement of the security projects to consider new threats and vulnerabilities.

The risk factors are other important features that should be considered when estimating the cost of security projects. They are related to the risk associated to future security breaches in the operational period of the developed security solution and to the remaining residual risk after deploying the security solution. For the first type, it is necessary to develop a model that anticipates the evolution of risk, associated to the unpredictable evolution of vulnerabilities and threats over time, and integrates their variable severities in order to enhance the cost-effectiveness of the developed security projects. The second type of risk allows the improvement of the efficiency of security solution in the future, since providing a complete security solution is impossible due to the constraints of the allocated budget to the security managers.

Security Investment Models

Different aspects might be considered to improve the developed security investment models. First, it is noted that when designing an investment model, the main aim is set on the efficiency of the security solution to protect the information system regardless its usefulness and its added value for the company's shareholders. It is, thus, more useful to develop a model that allows the achievement of its primary objective and to yield profit through including new parameters related to creation of value for the shareholder (such as dividends, profitability of funds, governance and financial transparency), in addition to parameters associated to the evolution and dynamicity of vulnerabilities and threats.

The second point to deal with concerns the security investment when private data are protected by outsourcing firms. In this case, the type of the subcontracting firms has an impact on the investment computation. This type is related to the degree and the nature of control (i.e. partial, global) over the outsourced resources (e.g., data, applications, services). In addition, related parameters to private business data should be taken into account as they could have significant impacts on determining the investment model, such as the value of the information to be protected, the degrees of sensitivity of this information to security attacks, the degrees of attractiveness of business data to attackers, etc.

CONCLUSION

The project management is an important task to be performed when dealing with security project to avoid project failures. Different researches assume that security and software projects are managed in the same way using the same tools and techniques. Nevertheless, it is noted that there are differences between the two projects and additional issues should be considered when managing security project.

A number of study were conducted around different aspects of security projects but remaining issues related specifically to the dynamicity and evolution of the environment, attacks, and system resources are needed to be resolved in order to develop an efficient cost estimation model and to better assess the budget allocated to security task. Therefore, additional efforts still needed.

This chapter focuses on the security project management and the existing cost estimation models. It also presents a review of the security investment models and describes the latest developed works. In addition, the chapter underlines the relationships between cost estimation and security investment when designing security projects and examines the future directions for the development of efficient models.

KEY TERMS AND DEFINITIONS

Awareness: Is the extent to which an individual who has access to the information system assets is aware of. It is related to the importance of security and dangerousness of attacks, the enterprise's security requirements, and its responsibilities regarding the enforcement of security inside the information system.

Cost Estimation: Is an approximation of the probable cost of a project computed on the basis of the cost of all resources that will be charged to complete project activities.

Economic of Information Security: Is the discipline that applies different economic theories to resolve information security problems.

Information Security: Is the protection of the information system's resources from unauthorized access, use, disclosure, disruption, modification, perusal, inspection, recording or destruction.

Information System: Is a set of interconnected components (technology, process and people) that collect, process, store, and distribute information to sustain decision making and control in an enterprise.

Optimal Security Investment: Is the amount of investment which maximizes the Esperance of the gained loss and minimizes the risks of security attacks.

Project Management: Is a common framework providing managers with principles, techniques, and tools needed to manage project team effort efficiently and to meet successfully the enterprise's project objectives.

Residual Risk: Is a quantification of the risk or the degree of exposure that the protected information system will incur, after deciding to counter or eliminate known risk.

Security Attack: Is any form of malicious actions taken to harm the security of information system components. An action is classified as malicious with respect to the enterprise security policy.

Security Policy: Is a document that lays the framework for information system security of the enterprise. Through this framework, a security project team can draw intelligible objectives, plans, rules and formal procedures required to manage and protect the sensitive enterprise information system from different attacks.

Security Project: Is a set of activities that aim to protect and secure an information system from attacks and potential threats.

Security Risk: Is the likelihood that enterprise assets (i.e. information, systems and network infrastructures, data, programs and applications) be targeted by a successful attack.

Threat: Is an indication about a potential event that can harm the security of the protected resource. A threat can turn to a security attack once a vulnerability that can be exploited is found.

Vulnerability: Is a defect or weakness in information system's assets or mechanisms, which could lead to a security breach when exploited by malicious entities.

Development of Personal Information Privacy Concerns Evaluation

Anna Rohunen

University of Oulu, Finland

Jouni Markkula

University of Oulu, Finland

INTRODUCTION

Personal data collection and utilization are increasingly taking place today as a part of the application of personal data intensive systems and services. Both individuals and data collecting organizations benefit from this. Personal data are collected and processed by private companies and public organizations for various purposes, for example, for delivery of more personalized services and for marketing. Despite its usefulness, extensive personal data collection raises privacy concerns among data subjects, and these concerns are also discussed in public very often. For example, vehicle GPS tracking-based kilometer taxation has been recently under debate. This debate has shown that vehicle tracking data can also be used for purposes other than taxation, and that it can be combined with other data, for example, for producing traffic information services by private or public organizations. Information privacy concerns derive from data subjects' desire to not be monitored, and their worries about the consequences of the use of their data. Privacy concerns often decrease data subjects' willingness to disclose their personal data or to use services that require personal data disclosure. For this reason, privacy concerns may lead to non-adoption of new services and technologies, dropping out of them, or a decline in data disclosure (i.e., omitting data or providing false information). To address these issues, we need to understand how to evaluate

privacy concerns in current and future evolving service development contexts. We need insights into how privacy concerns have been evaluated in earlier contexts in order to adapt evaluations to new contexts.

In many countries, legislation sets the foundation for protecting personal data privacy and provides a framework for implementing privacy protection methods and technologies. However, it does not really suppress privacy concerns of the data intensive services' users. People's privacy concerns need to be understood to apply legislation in present-day data collection contexts, characterized by rapid technological change, expanded data collection, diverse uses for collected data, and possibilities to monitor individuals' behavior and combine data from different sources. This understanding can be gained with well-designed *privacy concerns evaluation instruments*. When privacy concerns are evaluated and analyzed, their negative effects on personal data disclosure can be mitigated. In this way, more efficient promotion of personal data intensive services and realization of their benefits for both service users and providers can be reached. In practice, privacy concerns can be addressed by various means based on their evaluation. First, the means of privacy protection and the real risks of data disclosure can be communicated to the data subjects and the general public. Second, data subjects can be given control over their information, and benefits can be offered to them for disclosing information.

Third, privacy-preserving systems and service design can be facilitated by taking service users' privacy concerns into account.

Several researchers have contributed to development of information privacy concerns evaluation instruments since the beginning of the 1990s. Due to evolving technologies and new data collection contexts, the existing instruments do not necessarily match data subjects' privacy concerns anymore. Therefore, the validity of these instruments should be examined for their subsequent development and use. We have addressed this challenge by carrying out an analysis of the most widely used privacy concerns evaluation instruments. Through this analysis, we have gathered information specifically on different aspects of individuals' privacy concerns (referred to as privacy concerns' *dimensions* in the instruments) and how they should be taken into account in the instruments' development. We have identified both privacy concerns' core dimensions that have remained unchanged in the evaluations with time and the types of context dependent dimensions to be incorporated into evaluation instruments. When summarizing the results of our analysis, we pay attention to the fact that in addition to being valid and up-to-date, evaluation instruments should also be made easy-to-use enough. In this way, they can be applied to the practical development of personal data intensive services.

In this article, an overview of the existing privacy concerns evaluation instruments will be given and complemented with an outline of their future development. At first, the historical development of privacy concerns evaluation instruments is described, and the most widely used key evaluation instruments from different decades are introduced. Next, an analysis of these key evaluation instruments is presented, focusing on the privacy concerns' dimensions and their changes with technological development and evolving data collection contexts. After this, recommendations on how to utilize the existing evaluation instruments are given, as well as suggestions for future

research dealing with validation and standardization of the instruments.

BACKGROUND

Opportunities for automatic processing of personal data for business purposes have evolved from the first electronic records in the 1950s to present-day comprehensive data collection and processing systems with different data sources and diverse uses. With technological development enabling this change, companies are showing increasing interest in personal data use for developing their products and services and making their operations more effective.

The rapid progress of information technology in the 1960s enabled big enterprises to, for the first time, establish extensive databanks for their customers' personal data. Later on, data warehousing type systems made it possible to easily combine, process, and analyze the collected data for corporate decision making. Along with these changes, discussion on information privacy was evoked, bringing out the need for personal data protection (cf. Westin, 1967). With the launch of e-commerce and other Internet-based services in the mid-1990s, again, new and expanded opportunities for collecting and utilizing personal data of these systems' users appeared. For example, compared to traditional customer records, customers could now be profiled and their preferences could be identified in more detail based on their clickstream. A few years later—specifically, after the introduction of smart phones—development of location and mobility data-based services gained momentum, creating possibilities for gathering even more detailed and extensive data on individuals and their behavior. As a whole, nowadays, the current technology makes possible large-scale personal data collection, integration of data sources of different types, and combination of separate data pools for diverse uses of the collected data. This enables the production of big data that is highly

valuable to society, as it has the potential to boost both economic growth and utility for individuals. Increased efficiency, quality, and productivity can be reached, and customers' needs can be better met through big data use. On the other hand, it is clear that there are substantive privacy issues associated with the present-day personal data collection. These issues are being regulated by legislation which needs to be adapted to individuals' privacy behavior and personal data collection technologies and contexts. The need for regulation of automatic data processing with ongoing technological development is reflected, for example, by the General Data Protection Regulation reform in the EU (European Commission, 2012).

Evaluation of individuals' information privacy concerns is not necessarily a straightforward task, as people may be concerned about different aspects of privacy (which are usually referred to as privacy concerns *dimensions*). There has been a tendency to learn to understand and take into account privacy concerns for decades, and these concerns have been measured in opinion polls and as a part of research studies as well. However, privacy concerns evaluation instruments and their dimensionality have been developed in a methodical way only since the beginning of the 1990s. Prior to this, information privacy concerns evaluations were relatively fragmented in nature, in that they considered privacy concerns to be either a unidimensional construct or varying in their dimensions. Culnan (1993) presented some burning questions related to secondary use and publishing of personal data for direct marketing purposes in the off-line context. She stated that companies collecting consumers' personal data may find it difficult to pursue the opportunities provided by data collection technologies if they do not comply with information practices responding to consumers' privacy concerns. This challenge has been extensively studied in the literature on information privacy concerns and privacy behavior, indicating that individuals' privacy concerns often lead them to decline to disclose personal data if not being informed of appropriate privacy

practices. For this reason, it is crucial to have well-designed, validated evaluation instruments for information privacy concerns evaluation. The development of these instruments initially focused on collection of off-line personal data such as customers' demographic and purchase data (e.g., Culnan, 1993; Smith et al., 1996; Stewart & Segars, 2002). With the development of e-commerce and Internet-based services, evaluation instruments specific to the Internet context started to become popular (e.g., Malhotra et al., 2004; Dinev & Hart, 2004; Castaneda et al., 2007). These instruments' items were adapted from the existing instruments, taking into account online threats and unforeseen uses of information. As for individuals' location and mobility data collection through smart mobile devices with GPS tracking, questionnaire items on continuous, large-scale mobility data collection were further developed in some studies on privacy behavior in this context (e.g., Junglas et al., 2008; Xu & Gupta, 2009; Raschke et al., 2014). People are exposed all the time to the possibility of increasingly severe privacy losses due to present-day production of big data together with mobile devices' and body sensors' collection of personal data. As data collection of this kind enables continuous monitoring of individuals and their health and physical condition, data that are often considered highly sensitive information, the need for checking the validity of the existing privacy concerns evaluation instruments is increasing.

Information privacy concerns are changing along with evolving personal data collection contexts and the trend towards increasingly comprehensive data collection and modeling of data subjects' behavior. People's attitudes towards data use may change as it becomes a part of our everyday life and we accommodate to the present-day inclusive data collection culture (cf. Nosko et al., 2010). On the other hand, people are continuously exposed to privacy related news and public discussions and hence are increasingly aware of possible privacy issues regarding personal data use. All these aspects should be taken into account when

developing privacy concerns evaluation instruments for new personal data intensive services; in other words, evaluation instruments should be adapted to changes in evaluation contexts and the data disclosure culture.

PRIVACY CONCERNS EVALUATION IN EVOLVING PERSONAL DATA INTENSIVE SERVICES

Present-day and future personal data intensive services are challenging privacy concerns evaluation due to evolving technologies and new data collection contexts. We need to understand existing evaluation instruments' historical evolution to further develop and validate them. Therefore, we present a historical description and analysis of key evaluation instruments and their dimensions in the literature. Our description and analysis covers the most widely used evaluation instruments that date back to different decades and represent different data collection contexts.

Evolution of Privacy Concerns Evaluation Instruments

In the times of electronic records and data warehousing systems, the data collected from customers typically consisted of their contact information and demographic and purchase data. These data were not only used for customer service and companies' operational and strategic aims, they were also often sold for secondary purposes, specifically to direct marketing companies. At the beginning of the 1990s, Culnan (1993) conducted a survey on data subjects' attitudes towards secondary use of their personal data for direct marketing. She identified two dimensions of privacy concerns: *loss of control* over information and *unauthorized secondary use* of information. Culnan's work was followed by an instrument developed by Smith et al. (1996) for evaluating data subjects' concerns about data collecting companies' organizational information practices for personal data use. Smith

et al. identified four dimensions of information privacy concerns, one of them similar to Culnan's dimension of *unauthorized secondary use*. The other three dimensions were *data collection* (i.e., whether excessive data are collected on a data subject), *improper access* to personal information (i.e., within an organization, whether a person without the "need to know" is able to access personal information stored in the files), and *errors* in personal data (e.g., accidental errors or obsolete data). Stewart and Segars (2002) further developed the instrument by Smith et al. Their results suggested that data subjects are concerned about all of the dimensions of organizational information practices simultaneously, rather than any one dimension in particular. Stewart and Segars also found that separate dimensions are interrelated and that the *control* over the information dimension possibly accounts for these interrelationships.

At the beginning of the 2000s, new information privacy concerns evaluation instruments, intended for the Internet context, were introduced. An instrument by Dinev and Hart (2004) for Internet users' privacy concerns evaluation was based on the instruments by Smith et al. and Culnan and Armstrong (1999), and these existing instruments were modified to reflect the nature of the online context. The results by Dinev and Hart suggested an instrument with only two privacy concerns' dimensions: information *finding* on the Internet (i.e., possibilities to track data subjects' activities and their personal information) and information *abuse*. Dinev and Hart also measured *perceived ability to control* information disclosure, recognizing it a separate construct from privacy concerns. However, they pointed out that different results could have been obtained if *need for control* was measured instead of *perceived ability to control*, and that need to control information disclosure may already have been captured by privacy concerns. Almost at the same time as Dinev and Hart, Malhotra et al. (2004) presented their instrument for evaluating Internet users' information privacy concerns related specifically to data disclosure in e-commerce. They proposed three privacy con-

Table 1. Comparison of the key information privacy concerns evaluation instruments

Dimensions Incorporated Into the Instruments	Unauthorized Secondary Use	Control	Collection	Errors	Improper Access	Awareness	Finding	Abuse
Culnan (1993)	x	x						
Smith et al. (1996)	x		x	x	x			
Stewart & Segars (2002)	x	x	x	x	x			
Dinev & Hart (2004)		(x)					x	x
Malhotra et al. (2004)		x	x			x		
Castaneda et al. (2007)	x		x					

cerns' dimensions by drawing on social contract theory: *collection* of personal information, *control* over the collected information, and *awareness* of information use. The items incorporated into the collection dimension were based on Smith et al. and adapted to the Internet context by slightly changing their wording. Castaneda et al. (2007) further developed privacy concerns' measurements in the Internet context. They aimed to distinguish between general Internet privacy concerns and e-commerce web site-specific privacy concerns. Two dimensions were identified for these concerns, namely concern for personal information *collection* and concern for personal information *use*, the latter one corresponding to *unauthorized secondary use*. Castaneda et al.'s instrument items in the *collection* dimension include the aspects of *loss of control* and *improper access*, reflecting the intrusive side of the Internet context.

The recent development of information privacy concerns evaluation comprises themes such as identification of different conceptualizations of privacy concerns (Hong and Thong, 2013), revisiting of existing privacy concerns evaluation (Sipior et al., 2014), privacy concerns' dependency on the types of digital applications for which data are disclosed (Bergström, 2015), and comparison of different privacy concerns evaluation instruments as a part of a privacy behavior model (Fodor and Brem, 2015). All this research reflects the nature of present-day personal data collection, characterized by high volume and continuity of data collection, digital traces, and possibilities of data mining.

It is worth noting that aspects corresponding to privacy concerns' dimensions are defined in data privacy legislation, but from the data controller's (the body collecting data and legally responsible for its processing) viewpoint instead of the viewpoints of individuals whose data are collected. The aforementioned EU privacy regulation aims to minimize personal data collection by requiring specified, predetermined, and legitimate purposes of use (cf. *collection*, *finding*, and *abuse*). It also sets conditions on data disclosure to third parties (cf. *unauthorized secondary use*), imposes data subjects' right of access to their data and right to demand its rectification or removal (cf. *control*), and sets right to obtain rectification of incorrect data (cf. *errors*). Further, the regulation requires implementation of appropriate technical and organizational data protection measures (cf. *improper access*), informed consent for data processing (cf. *awareness*), and provision of data subjects with specified information on processing of their data (cf. *awareness*). It should be borne in mind, however, that not all individuals' information privacy concerns are covered by legislation. This applies specifically to concerns brought up by the new data collection contexts.

A comparison of the described key information privacy concerns evaluation instruments, as regards their dimensions, is presented in Table 1.

Information privacy concerns evaluation instruments by Smith et al. (1996) and Malhotra et al. (2004) have served as standard evaluation instruments in both offline and Internet contexts.

Subsequent studies have often used them as a starting point or reference for their instrument development. The instruments by Smith et al. and Malhotra et al. have been adapted into the evolving data collection contexts by modifying the wording of their items and adding new items relevant to the context. When moving to the Internet context, items originally dealing with companies' data collection and privacy practices in the offline context have been reworded to reflect online data collection. New items on Internet threats incorporated into the instruments deal with stealing or misuse of submitted information, uncertainty about its subsequent use, and continuous tracking of individuals' actions on the Internet. Furthermore, a tendency to adapt instruments better to increasing personal data collection and monitoring of individuals' behavior can be identified in some recent studies (cf. Mao & Zhang 2013, Raschke et al. 2014).

Analysis of Privacy Concerns' Dimensions

Three privacy concerns' dimensions are incorporated into most evaluation instruments regardless of their application contexts: extent of *data collection*, *unauthorized secondary use* of information, and *control* over personal information. Specifically, *collection* is relevant to different kinds of data collection contexts, and it possibly captures the tendency toward increasingly intrusive data collection. It is worth noting that when adapting the instruments to the new contexts, the *collection* dimension has specifically been modified. In the instrument by Smith et al., developed for off-line contexts, the *collection* dimension's items reflect data subjects' views on and reactions to personal data collection by companies, that is, whether data collection and its extent bothers them, and whether they hesitate to disclose their data. Malhotra et al. adapted these items to their online context study. Castaneda et al., instead, based their items on the possibilities of non-transparent and unauthorized data collection in online contexts.

Unauthorized secondary use, which mainly refers to direct marketing purposes in early evaluation instruments, is a relevant dimension in present-day data collection contexts as well due to the diverse uses and possibilities of combining the data. This dimension has remained relatively unchanged despite the transition in data collection contexts. It deals with data use and sharing without the data subject's permission and using of it for other purposes that it was collected for. *Control* over personal information is a key concept related to the definition of information privacy and has hence been a part of privacy concerns evaluations since their inception. It can be said that its role in privacy protection is becoming even more important with the evolution of data collection contexts and individuals' will to decide the types and uses of their data they should disclose. The *control* dimension reflects data subjects' need for control, their perceptions of loss of privacy, and their opinions on the importance of being able to make decisions about their data collection and use.

Unlike the three dimensions described above, some privacy concerns' dimensions seem to be context dependent. *Awareness* about the use and processing of collected data is an aspect closely related to *control* because the ability to control information requires knowledge and understanding about its uses. This dimension likely becomes more important with increasing, more diverse data collection. It is noteworthy that the instruments intended for online contexts do not incorporate dimensions of *improper access* or *errors* that reflect data subjects' demand for procedures to protect personal data and to ensure its accuracy. These dimensions have been highly relevant to earlier offline contexts' data collection with electronic records accessible to companies' employees and prone to errors with regard to data input. In present-day contexts, *improper access* to data can be considered included in concerns about tracking. This idea may support the exclusion of the *improper access* dimension from the instruments when more parsimonious and simple instruments are needed.

In conclusion, it seems that there are some core dimensions to be incorporated even in present and future privacy concerns evaluation instruments. On the other hand, the relevant dimensions may be dependent on the characteristics of the data collection context. Interrelationships between dimensions and their overlapping should also be taken into account when developing evaluation instruments.

SOLUTIONS AND RECOMMENDATIONS

Information privacy concerns evaluation instruments can be used to gain an understanding of users' privacy concerns regarding personal data intensive services. The existing instruments provide a solid, validated base for the development of privacy concerns evaluation. For this reason, they should be used as a starting point for evaluations and then adapted to the context in question. Our analysis showed that information privacy concerns' core dimensions are incorporated into privacy concerns evaluation instruments independently of the data collection context. These core dimensions are extent of *data collection*, *unauthorized secondary use* of information, and *control* over personal information. Adaptation of evaluation instruments to the data collection context can be done by varying the rest of the instruments' dimensions. Privacy concerns' dimensions specific to different data collection contexts typically reflect the extent of data collection, the level of data collection's continuity (i.e., its potential for tracking users' behavior either online or in a physical environment), and diversity of subsequent uses of the collected data. It is worth noting that in continuously evolving data collection contexts, new privacy concerns' dimensions may emerge regarding the context's nature and, for example, perceived sensitivity of data. In our research, we have identified the studies presented in this article as the key studies

involving evaluation instruments that should be taken into account in privacy concerns evaluation.

FUTURE RESEARCH DIRECTIONS

This article has presented an analysis of key privacy concerns evaluation instruments and their dimensions. Due to technological changes and new data collection contexts, privacy concerns' dimensions should be investigated even in future research, specifically to identify the context-specific dimensions to be applied in the evaluations. As the literature contains a large number of studies on information privacy concerns evaluation, the present analysis should be advanced by analyzing these studies systematically. In addition to the scientific literature, it would be reasonable to extend the analysis to the privacy aspects present in legislation. Similarly, people's changing attitudes towards personal data collection as a part of cultural change should be taken into account in future research. In this way, a validated, standardized, and easy-to-use evaluation framework could be constructed for facilitating application of knowledge to different and new data collection contexts. Relations between separate privacy concerns' dimensions could be another relevant topic of research in order to determine whether different dimensions of privacy concerns always need to be incorporated into the evaluation instruments or whether there are situations in which simplified instruments could be used.

CONCLUSION

This article explored how existing information privacy concerns evaluation instruments could be adapted to match data subjects' privacy concerns in evolving data collection contexts. An overview was presented of the historical development of the information privacy concerns evaluation instruments, spanning a period from the beginning of

the 1990s, with its data warehousing systems, to the 2000s, with its continuous monitoring of individuals' actions on the Internet. This overview was followed by an analysis of the key evaluation instruments, which provided insight into their validity for present-day personal data collection contexts. The analysis focused on the dimensions incorporated into privacy concerns evaluation instruments. It showed that these dimensions have changed with evolving data collection contexts and the tendency toward extensive, continuous personal data collection. However, there are core dimensions that seem to be valid even for current data collection contexts. These dimensions, namely extent of *data collection*, *unauthorized secondary use* of information, and *control* over personal information, can be used as a starting point for privacy concerns evaluation. Evaluation should then be adapted to the data collection context in question by varying the instrument's dimensions. Regarding future research, it is suggested to start construction of a validated, standardized, and easy-to-use evaluation framework for facilitating privacy concerns evaluations in different contexts.

KEY TERMS AND DEFINITIONS

Information Privacy: An individual's capability to control disclosure of information about him/her to others by determining the type, extent, uses, and users of the data to be disclosed.

Information Privacy Concerns: An individual's concerns about collection, processing,

and use of information about him/her, and about the related consequences.

Personal Data: Any information relating to an identified or identifiable natural person (“data subject”); an identifiable person is one who can be identified, directly or indirectly, in particular by reference to an identification number or to one or more factors specific to his physical, physiological, mental, economic, cultural, or social identity (EC Directive 95/46/EC).

Personal Data Intensive Services: Services substantially based on collection, processing, and utilization of users' personal data for service provision. These services can be produced by private companies, public sector organizations, or non-governmental parties.

Privacy Concerns Evaluation Instrument: A way or method to measure individuals' privacy concerns, for example, a survey.

Digital Video Watermarking Using Diverse Watermarking Schemes

INTRODUCTION

With the advent of internet in 1967, it has revolutionized the fields of communication and computer unlike anything before (Maity & Kundu, 2002). Since then it has grown exponentially and has become a vast information reserve. Nowadays people prefer to search the internet than looking into any book, to gain knowledge on the subject that intrigues them.

Internet has now become the easiest way of sharing information and with the growth of social networking sites, doing the latter with the masses has become even easier and it can be done quite briskly. People now buy storage spaces over the internet so that they can have access to their works from anywhere in the world. With the increase of information and digital content over the internet the need and necessity of multimedia security and copyright protection arises (Agrawal, Gupta, & Chakraborty, 2015; Natarajan & Makhdumi, 2009). So in order to stop theft and lose of fidelity of digital content we need to develop techniques to safeguard the digital contents (Lai, & Tsai, 2010). Digital Watermarking is one such technique that is used for copyright protection of digital media.

BACKGROUND

What Is Digital Watermarking?

Copyright Protection incorporates a logo or some ownership information into the digital media without affecting its perceptibility (Agrawal, Gupta, & Chakraborty, 2015; Yeo, & Yeung, 1997). Hence, in case of a conflict, the logo can effectively be extracted from the digital media in order to claim the ownership rights. Watermarking is a process of embedding some data called the watermark or the digital signature into the digital media (Sinha, Bardhan, Pramanick, Jagatramka, Kole, & Chakraborty, 2011). Here the researchers will primarily focus on Digital Video Watermarking.

What Is Digital Video Watermarking?

Digital Video Watermarking is a method of copyright protection of videos in which a watermark is added to the original video without affecting its perceivable quality (Yeo, & Yeung, 1997; Doerr, & Dugelay, 2003). For a watermarking scheme to be used for copyright protection, it should fulfill two criterions i.e. it must be robust against attacks like signal processing and lossy compression and

it should not lead to loss of fidelity (Al-Khatib, Al-Haj & Lama-Rajab, 2008). Some watermarking techniques require the original video for the detection of the watermark. This is called a non-blind watermark detection method while there are some watermarking techniques which do not require the original video for watermark detection (Maity & Kundu, 2002). This is called blind watermark detection method and is usually preferred.

Types of Watermarks

As per human perception the watermark can be of three types, visible, invisible and dual. (Potkar, & Ansari, 2014). As the name suggests, a visible watermark is perceivable but an invisible watermark is not. For e.g. a watermark is to be added to an image or a video then in case of a visible watermark, the watermark can be seen on the image or on the video frames but in case of invisible watermarks, a layman would not be able to differentiate whether a watermark has been added to the digital media or not. A Dual watermark incorporates both visible and invisible watermarks to the video. Here the invisible watermark is kept as a backup for the visible watermark. The researchers' can choose anyone of them as per our requirements and necessities.

Factors to be Considered While Embedding a Watermark on a Video

While embedding a digital image watermark on the video the following things should be kept in mind:

1. **Imperceptibility:** The watermark should not be visible in the copyrighted video (Maity, & Kundu, 2011).
2. **Robustness:** It should be impossible for the attacker to detect or extract or manipulate the watermark (Maity, & Kundu, 2011).
3. **Fidelity:** The perceivable quality of video should not degrade.
4. **Security:** It should be impossible to generate a duplicate of the authentic watermark

to claim false ownership. The watermark should also be non-invertible.

5. **Verification:** The watermark can be extracted from the watermarked video to prove ownership.
6. **Constant Bit Rate:** As the transmission channel bandwidth has to be obeyed so the watermarked video should also have the same bit rate.

Classification of Video Watermarking

Many Video watermarking schemes have been proposed till date, while some are deployed on uncompressed videos, the others are deployed on the compressed versions (Hartung, & Girod, 1998; Meng, & Chang, 1998). Video Watermarking is classified into two categories based on the methods of embedding the watermark bits in the host video. The two categories are:

1. **Spatial Domain Technique:** In this method the watermark can be embedded and detected by directly manipulating the pixel intensity values of the video frame (Sinha, Bardhan, Pramanick, Jagatramka, Kole, & Chakraborty, 2011).
2. **Transform Domain Technique:** Here the spatial pixel values of the host video are altered according to some predefined algorithm. The watermark is dispersed throughout the host video and this makes the technique robust against malicious geometric attacks (Sinha, Bardhan, Pramanick, Jagatramka, Kole, & Chakraborty, 2011).

Thus, transform domain watermarking schemes ensures more imperceptibility, randomness in the distribution of the watermark and have also proven to enhance robustness against geometric attacks. Hence, it is better to use the transform domain technique rather than the spatial domain technique (Sinha, Bardhan, Pramanick, Jagatramka, Kole, & Chakraborty, 2011).

Types of Attacks on Video Watermarks

A successful attack is one in which the watermark has been modified in a manner to prevent its successful extraction without affecting the quality of the video significantly. A successful attack does not mean that the digital media cannot be restored to its original state but it means that watermark detection and extraction techniques are no longer useful for claiming ownership rights as the watermark has been modified (Potkar & Ansari, 2014). The attacks are of two types (Singh & Chadha, 2013):

1. **Intentional Attacks:** These attacks are done deliberately to prevent successful extraction of the watermark. Types of Intentional attacks are:
 - a. **Geometric Attacks:** Here minor geometric distortions are made to the video frames to de-synchronize the extraction procedure. The changes induced in the video frame can be negligibly perceived but it prevents successful extraction of the watermark (Potkar & Ansari, 2014). It instills attacks like rotation, scaling, etc. to the video frames. This type of attacks usually affects each frame of the video (Voloshynovskiy, Pereira & Pun, 1999; Husain, 2012).
 - b. **Statistical Attacks:** Videos are susceptible to attacks which are not applicable in the case of images. These attacks take advantage of this inherent redundancy between the frames to remove the watermark. Attacks like frame averaging, frame swapping and statistical analysis comes under this head (Potkar & Ansari, 2014).
 - c. **Protocol Attacks:** This type of attacks try to destroy the digital content itself rather than trying to remove or destroy the watermark. Examples are Copy attack and watermark inversion.

In copy attack the watermark is copied from one frame to another without any knowledge of the watermarking technique used. A watermarking scheme is not resistant to copy attack then the watermark used for verification cannot be trusted as it might have been copied from somewhere else (Potkar & Ansari, 2014).

- d. **Removal Attacks:** This type of attacks usually employ filtering techniques to remove the embedded watermark. Its examples are spatial averaging filter, Wiener de-noising filter (Potkar & Ansari, 2014).
2. **Unintentional Attacks:** These attacks are introduced into the system by normal signal processing and compression but are not done intentionally. Types of Unintentional attacks are (Potkar & Ansari, 2014):
 - a. Analog to Digital and Digital to Analog Conversion.
 - b. Scaling and Cropping Operations.
 - c. Frame Rate Conversion.
 - d. Aspect Ratio Conversion.
 - e. Quantization,
 - f. Compression, and
 - g. Noise Addition.

Applications of Video Watermarking

According to Van Huyssteen's thesis the applications of video watermarking are numerous but they can be brought down under six heads, they are:

1. **Transaction Tracking:** It is used to track the manner in which the content was distributed in the system or through multiple points. In situations where illegal distribution of data occurs then it should be ideally possible for us to track the source from where the distribution has occurred in order to identify the misappropriating party. This is done by embedding a unique identifier into the media at the time of playback which can be

extracted at a later time (Potkar & Ansari, 2014; Singh, Jain & Jain, 2013).

2. **Broadcast Monitoring:** It is used by the broadcasters or content owners to check if their content had been completely broadcasted or just a part of the material had been used. The watermark is automatically extracted to verify the latter. The watermark is usually embedded by the content owner itself while it is extracted either by monitoring sites in the broadcast chain or by a third party at the receiving end (Potkar & Ansari, 2014; Singh & Chadha, 2013).
3. **Content Authentication:** The content is watermarked with a semi-fragile watermark, which is designed to be affected by signal transformations. So on tampering with the content the watermark gets either destroyed or modified and can be used to prove that the content is not authentic. It is used for detecting tampering of the content (Potkar & Ansari, 2014; Singh, Jain & Jain, 2013).
4. **Ownership Identification:** The watermark is extracted from the digital content and verified to prove or claim ownership rights in case of any conflicts. The pirates may also embed their own watermark to the digital content and in such a situation it becomes quite difficult to tell that which one is the original watermark. This phenomenon is also termed as ownership deadlock problem (Potkar & Ansari, 2014; Singh, Jain & Jain, 2013).

Video Watermarking Schemes Currently in Use

The transform domain techniques which are commonly being used today are Discrete Wavelet Transform (DWT), Discrete Cosine Transform (DCT), Discrete Fourier Transform (DFT) (Jiansheng, Sukang & Xiaomei, 2009; Chaturvedi & Basha, 2012; Rahman, 2013). There are other techniques as well like Discrete Walsh Transform, Discrete Hartley Transform (DHT), Discrete

Kekre Transform (DKT), Singular Value Decomposition, Principal Component Analysis, etc.

These techniques are often combined to form new video watermarking schemes so as to produce better results. For example DCT along with DWT (Jiansheng, Sukang & Xiaomei, 2009), or DWT along with SVD and PCA (Sinha, Bardhan, Pramanick, Jagatramka, Kole, & Chakraborty, 2011) forms different watermarking schemes and the list continues. The basis of comparison of these techniques is by calculating the Peak Signal to Noise Ratio (PSNR) values and Normalization Coefficient (NC) value. PSNR gives us a measure about the imperceptibility of the watermark in an attacked video frame. The higher the PSNR values higher is the imperceptibility (Sinha, Bardhan, Pramanick, Jagatramka, Kole, & Chakraborty, 2011). NC is used to find the similarity between the extracted and original watermark. Its peak value is 1. It is used to make judgments on extraction fidelity (Sinha, Bardhan, Pramanick, Jagatramka, Kole, & Chakraborty, 2011). So the higher the PSNR and NC values, better is the watermarking scheme.

Discrete Wavelet Transform

Discrete Wavelet Transform or (DWT) is used widely in the field of signal processing. A two-dimensional DWT is a combination of two single 1-D DWT's applied to both the horizontal and vertical directions. 2-D DWT is used to decompose the image into lower resolution approximation sub-band (LL) as well as horizontal (HL), vertical (LH) and diagonal (HH) detail components, (Figure 1). The embedding process is carried out in the LL sub-band to make the watermarked image withstand lossy compression (Shaikh, Khan & Kelkar, 2012).

Discrete Fourier Transform

Discrete Fourier Transform or DFT is one of the oldest techniques of image compression. A Fourier Transform converts a signal into sinusoids. It takes

Figure 1. DWT sub-bands

as input a time-continuous signal and its output is a signal in frequency-domain. However, DFT takes as input samples of the signal in time-domain and converts them into samples in frequency-domain. DFT is easily calculated in computers using Fast Fourier Transform or FFT algorithms. The time complexity in this calculation is $O(N \log N)$.

Discrete Cosine Transform

Discrete Cosine Transform (DCT) is another commonly used transform technique in signal processing. It aims at converting an image from its spatial domain to frequency domain in order to make it robust against different attacks like contrast adjustment, low pass filtering, etc. (Chaturvedi & Basha, 2012). Discrete Cosine transform is defined by the equations, (1) and (2).

$$f(mn) = a(j)a(k) \sum_{m=0}^{N-1} \sum_{n=0}^{N-1} f(mn) \cos\left[\frac{(2m+1)j\pi}{2N}\right] \cos\left[\frac{(2n+1)k\pi}{2N}\right] \quad (1)$$

and the Inverse Discrete Cosine transform is given as:

$$f(mn) = \sum_{m=0}^{N-1} \sum_{n=0}^{N-1} a(j)a(k) f(mn) \cos\left[\frac{(2m+1)j\pi}{2N}\right] \cos\left[\frac{(2n+1)k\pi}{2N}\right] \quad (2)$$

Singular Value Decomposition

Singular Value Decomposition is a technique for expressing a matrix as a product of a diagonal matrix and two orthogonal matrices (Seema, 2012). The SVD of a given image A in the form of a matrix is defined by equation (3).

$$A = USV^T \quad (3)$$

where U and $V \in \mathbb{R}$ and are $N \times N$ unitary matrices and $S \in \mathbb{R}$ with dimensions $N \times N$ is a diagonal matrix.

COMPARISON BETWEEN DIFFERENT SCHEMES

1. **DFT and DWT:** DFT is helpful in determining the frequency components present in a

Figure 2. Representation of singular value decomposition

$$SVD(A) = \begin{bmatrix} U_{1,1} & \dots & U_{1,n} \\ U_{2,1} & \dots & U_{2,n} \\ \vdots & \vdots & \vdots \\ U_{n,1} & \dots & U_{n,n} \end{bmatrix} \begin{bmatrix} \sigma_1 & 0 & 0 & 0 \\ 0 & \sigma_2 & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \sigma_m \end{bmatrix} \begin{bmatrix} V_{1,1} & \dots & V_{1,n} \\ V_{2,1} & \dots & V_{2,n} \\ \vdots & \vdots & \vdots \\ V_{n,1} & \dots & V_{n,n} \end{bmatrix}^T$$

signal. It can even be used on a signal of variable frequency components. However, it does not show the temporal localization of these frequency components. This can be achieved by using DWT which illustrates which frequency component of the signal is present at a given time. DWT can, thus, also be applied on non-stationary signals. Hence, DWT has replaced DFT in most of the applications because of its extended usability. The PSNR value from a watermarking scheme using DWT is better than that of a scheme using DFT.

2. **DWT and SVD:** DWT is the outcome of the electrical treatment being given to an image. SVD is a procedure applied to a matrix to approximate some values in the final SVD matrix with a view of minimizing the useful data part of the original matrix. Here, an image is treated on the basis of its storage in a system, i.e., in the form of a matrix. It is to be noted that the original data is subject to manual alterations and the SVD procedure may not always yield the desired results. The same is not true for DWT where the user cannot meddle with the electrical signal directly.

Conventional Watermarking Methodology

The original watermarking methodology involved the application of a single decomposition technique with the algorithm to embed the watermark. Eventually, a combination of two or more techniques began being used to yield better results in terms of the PSNR. The combinations included DFT-DCT, DWT-DCT, DWT-SVD, etc. (Podilchuk, & Delp, 2001). Here, one decomposition algorithm followed the other. However, in video watermarking applications, the same watermarking scheme(s) were used for all video frames, with the fidelity of the scheme being same for all the video frames. Thus, the researchers have developed a new idea to watermark digital videos with great diversity in the schemes.

Method Used

The researchers realized that the inherent property of videos being composed of frames could be used to improve the efficiency of watermarking algorithm in terms of its PSNR and NC values (Agrawal, Gupta, & Chakraborty, 2015). Thus, a Composite Watermarking Technique had been proposed where different watermarking scheme(s) could be applied to different sets of video frames. Then, the watermark could be extracted from each set of frames for all of them to be superimposed to give the final extracted watermark. The number of different sets of frames in which the video is divided and the manner in which the sets are formed depends on whatever seems suitable.

Suppose a video contains ' N ' frames and it is to be divided into ' n ' number of sets. There is a variable ' i ' whose value ranges from 1 to N and a variable ' k ' whose value is given by $(i \bmod n)$ and its value ranges from 0 to $n-1$. Thus, on performing modular function on every i^{th} frame, we obtain a value of k by the equation, $k = i \bmod n$ and allot i to the k^{th} set. This gives us n distinct sets $(0 - (n-1))$. Then for each different set, a different watermarking scheme(s) would be applied to all frames in it.

The researchers have implemented this watermarking technique by dividing the video into two sets of frames, to obtain two values of k as 0 and 1. The set corresponding to $k = 0$ is the set of even numbered frames and that corresponding to $k = 1$ is the set of odd numbered frames. Here, DWT has been applied to the odd numbered frames with a DCT transformed watermark while another scheme of SVD is applied to the even numbered frames. The extraction process again follows the same approach for dividing the frames and each set has its own extraction procedure. The final extracted watermark is obtained by superimposing the individual watermarks obtained from the different sets (Agrawal, Gupta, & Chakraborty, 2015). The algorithms for the aforesaid scheme are given in the next section.

Figure 3. The flow chart for the proposed method with $n=2$

Watermarking Algorithms

The algorithms proposed for embedding and extracting the watermark are given below (Agrawal, Gupta, & Chakraborty, 2015).

Step 1: Watermark Embedding

Step 1: Input the original video and extract the individual frames.

Step 2: For odd,-numbered frames follow algorithm 1, cited by Chaturvedi, N., & Basha, D. S. (2012). Comparison of Digital Image watermarking Methods DWT & DWT-DCT on the Basis of PSNR. *International Journal of Innovative Research in Science, Engineering and Technology*, 1(2).

Step 3: For even-numbered frames follow algorithm 2, based on SVD (Rahman, 2013; Seema, 2012).

Step 4: Combine the outputs obtained from step 5 of algorithm 1 and from step 6 of algorithm 2 to obtain the watermarked video.

Algorithm 1

Step 1: Input the watermark, change it to YUV form (Y component– stands for luminance, i.e. brightness of the color, U and V components determines the color) (gray scale) from RGB (Red - Green – Blue color model) form and extract the luminance or the Y component of it.

Step 2: Apply 2-D DCT to the extracted Y component.

Step 3: For every odd numbered frame, change it from RGB form to YUV form and apply 2-D DWT to the Y component of it.

Step 4: Resize the 2-D DCT transformed watermark according to the LL part of the image and embed it into the LL part with a strength alpha by equation (4).

$$LL1 = LL + \alpha * WM \quad (4)$$

Here, LL is the approximation image obtained from 2-D DWT, WM is the resized watermark matrix and LL1 is the watermarked approximation image.

Step 5: Reconstruct the original frame from LL1 by applying inverse 2-D DWT to the Y component and changing it back to RGB form.

Algorithm 2

Step 1: Input the watermark, change it from RGB to YUV form and apply SVD on the Y component of it.

Step 2: To the even numbered frames extracted from step 1 of algorithm 1, change the color format from RGB to YUV and extract the Y component of it.

Step 3: Apply SVD on the Y component of the frames.

Step 4: Embed the watermark into the frames with strength alpha (same as that in algorithm 1), using equation (5).

$$Sf1 = Sf + \alpha * Sw \quad (5)$$

Here, Sf is the singular matrix obtained from single value decomposition of the video frame, Sw is the singular matrix obtained through single value decomposition of the watermark and Sf1 is the final singular matrix.

Step 5: Reconstruct the Y component of the watermarked frame by applying equation (6).

$$Y1 = Uf * Sf1 * Vf' \quad (6)$$

where, Uf and Vf are the matrices obtained by SVD of the video frame.

Step 6: Change the watermarked frame obtained from YUV to RGB format.

Step 2: Watermark Extraction

Step 1: Input the watermarked video, together with the matrices, Uw and Vw obtained by performing SVD on the watermark image.

Step 2: Extract the individual frames. For odd-numbered frames, follow algorithm 1 for extraction, cited by Chaturvedi & Basha 2012.

Step 3: For the even-numbered frames, follow algorithm 2, cited in (Shaikh, Khan & Kelkar, 2012; Lai & Tsai, 2010).

Step 4: Resize the image matrices obtained from step 5 of algorithm 1 and from Step 5 of algorithm 2 to match their dimensions.

Step 5: Add the two images to obtain the final watermark image.

Algorithm 1

Step 1: Convert the frames from RGB TO YUV color format and separate the Y component.

Step 2: Perform 2-D DWT on the Y component.

Step 3: From the LL1 component obtained from step 3, obtain the watermark by the following equation.

$$WM = (LL1 - LL) / \alpha \quad (7)$$

Here, WM is the embedded watermark component and LL is the Y component of the original video frame.

Step 4: Perform inverse 2-D DCT on the output of step 4 to obtain the Y component of the watermark.

Step 5: Convert the YUV watermark image to RGB format.

Algorithm 2

Step 1: From the extracted even-numbered frames, convert the color format of the image from RGB to YUV.

Step 2: Obtain the Y component and perform SVD on it to get $Uf1$, $Sf1$ and $Vf1$.

Step 3: From $Sf1$, obtain Sw using the equation,

$$Sw = (Sf1 - Sf) / \alpha \quad (8)$$

Step 4: From Sw obtained from the previous step, reconstruct the Y component using the following equation,

$$Y = Uw * Sw * Vw' \quad (9)$$

where, Uw and the Vw are the matrices obtained from the SVD of the original watermark in the embedding process.

Step 5: Convert the image from YUV to RGB color format.

ALGORITHM RESULTS

The performance of the method mentioned above is measured in terms of the imperceptibility and robustness against possible attacks like filtering, noise addition, geometric attacks. The results are given in Table 1.

Peak Signal to Noise Ratio

The Peak Signal to Noise Ratio (PSNR) is a measure of the imperceptibility of the watermark. A high value of PSNR indicates more imperceptibility. The PSNR is calculated by (10).

$$PSNR = 10 \log_{10} (MAX_i^2 / MSE) \quad (10)$$

where MAX_i is the maximum possible value of a pixel in an image, MSE is the mean squared error which is calculated by (11).

$$MSE = \left(\frac{1}{mn} \right) \sum_{i=0}^m \sum_{j=0}^n [I(i, j) - I'(i, j)]^2 \quad (11)$$

where I and I' are pixel values at location (i, j) of the original and the extracted frames respectively.

Normalized Correlation Coefficient

The normalized coefficient (NC) is used to determine the robustness of the watermarking and has a peak value of 1 (Sinha, Bardhan, Pramanick, Jagatramka, Kole, & Chakraborty, 2011). The formula for calculating NC is given in (12).

$$NC = \frac{\sum_i \sum_j W(i, j) W'(i, j)}{\sqrt{\left(\sum_i \sum_j W(i, j) \right) \sqrt{\left(\sum_i \sum_j W'(i, j) \right)}}} \quad (12)$$

Where W and W' represents the original and extracted watermarks respectively.

Algorithm 1 and 2 are applied on a video, with the watermark and the extracted watermark is obtained.

The value of PSNR and NC for the proposed method is found to be 65.073dB and 0.547 respectively. These are the values without noise or any other attack. The values of both PSNR and NC under some of the attacks are given in Table 1.

FUTURE RESEARCH DIRECTIONS

The method used by the researchers holds immense potential in furthering researches related to the field of digital video watermarking. The use of composite methodology is highly promising. Many different schemes can be combined based

Table 1. Values of PSNR and NC under different attacks

Attacks	PSNR (dB)	NC
Gaussian Noise	53.397	0.509
Median Filtering	61.356	0.530
Poisson Noise	65.097	0.547
Salt & Pepper Noise	47.749	0.349
Sharpening Filter	45.532	0.968

on their productivity and also their compatibility with each other. The value of n can be varied to accommodate as many such combinations as required. When $n=1$, the same scheme can be applied to all the frames. Thereafter, combinations can be used.

CONCLUSION

The method used is potent of diversifying the use of the same set of schemes by applying them in the same or different sets of frames. The values of PSNR and NC are different for such diversification. For example, DWT and SVD can be applied to one set of frames in the given algorithm followed by DCT in another set of algorithms. The result is not the same as that for the demonstrative algorithm. The whole idea behind the use of such technology is in the improvement of the quality of the extracted watermark. Most of the attacks are more destructive for a set of schemes and cause negligible changes in the other. The choice of schemes should be such that the effects of different attacks cause different degrees of modification, so that the extracted watermarks from different sets could together yield a more resilient watermark.

KEY TERMS AND DEFINITIONS

Fidelity: The quality of the media (image, video and other) should not degrade on addition of the watermark to it.

Imperceptibility: The watermark should not be visible in the copyrighted video.

Robustness: The watermark should be robust against a wide range of attacks, so that the attacker cannot extract or manipulate the watermark.

Security: It should be impossible to create a duplicate watermark as this will lead to ambiguity during ownership verification.

Verification: The watermark can be extracted from the media and compared with the original watermark to prove ownership.

Watermark: It is a logo or digital signature which is used in watermarking.

Watermarking: It is the process of embedding a logo or digital signature in a media (image, video and other) for Copyright protection.

Ethical Computing Continues From Problem to Solution

Wanbil William Lee

The Computer Ethics Society, Hong Kong & Wanbil & Associates, Hong Kong

INTRODUCTION

Ethical Computing (Lee, 2015a) is instrumental in identifying and reaching a near-ideal solution to the problems arising from an environment that is *technology-driven information-intensive*. These problems raise techno-ethical issues, particularly information security concerns. *Post-implementation* and *post-contract* problems are cases in point. Many of these problems could have been avoided, occur; because we are either insensitive to or ignorant of their ethical implications. As a result, we could reach only a partial, compromised solution at best.

Ideally, the solution is not only technically efficient, financially viable and legal admissible, but also ethically acceptable, socially desirable, and in many situations environmental-friendly (the so-called *hexa-dimension criteria*) (Lee, 2015b & 2015d). In addition, the solutions sought must be capable of balancing the potential inter-conflicts among these demands or satisfying the five or six criteria. Given the conditions, a deep understanding of the basic ethical principles and the requisite technical know-how (the *requisite competence*) are necessary, and shifting our view on risk culminating in a new type of risk called techno-ethical risk or simply *ethical risk* and adopting a new tool of analysis to cater for the new risk (the *additive*) are also required (Lee, 2015c).

BACKGROUND

The Problem

Symptoms

Contemporary business organizations rely increasingly on information technology to accumulate and process the data needed to advertise their services and products, aiming at, for example, capturing market share and attracting customers. As a result, the marketplace becomes more transparent, and the consumers are better-informed thus more demanding. Consequently, more information is required, technology is increasingly relied upon to handle the increased amount of information generated and demanded, and new technological facilities such as call center and weblining (for marketing), and Big Data, Internet of Things, Cloud Computing (for communication and data management) are developed to aid business, to provide the processing power and contain the information explosion. This forms a vicious circle: *increase in demand for information leads to increase in reliance on technology, and increase in use of technology consumes and generates more information, culminating in the so-called technology-driven information-intensive phenomenon* (Lee, 2015d), raises ethical issues, and creates techno-ethical problems. Of these problems, many are commonly found in post-implementation and post-contract situations.

The one described below is typical of techno-ethical problems in post-implementation situations:

An online monitoring system was implemented successfully to replace an existing offline help-desk platform a high-tech facilities distributor. The new system enables help-desk staff to see exactly what is on the users' screens and to respond to users' requests for assistance quickly. Impressed by the fast response time and the increased user satisfaction, the executive vice president (EVP) asks the chief information officer (CIO) to have a copy of the system installed in her office for she wants to use this surveillance function to track down drug dealing allegedly occurring on company premises. The EVP's request raises indeed ethical dilemma for the Chief Information Officer (CIO).

Described in the following is another example of techno-ethical problems in post-contract situations:

The system specification (spec) was approved by the provider and client, and a contract duly signed. A senior project consultant assigned to the project discovered a fault in the inventory control function in the spec. The client is a fashion boutique so the fault is critical. The fault was confirmed after the consultant's site visit. Keep quiet or tell the boss or the client or both is a dilemma the consultant faces.

Causes

What causes this kind of problem is not the technology because the technology per se is neutral. What creates techno-ethical risks is the use of the technology. Two major reasons are cited here to make the point. First, we are insensitive to or ignorant of the ethical aspect of the problems and its ramifications because mainly of our lack of deep appreciation of the ethical principles. Second, we have hitherto treated risk as a technical, corporate/

personal matter when it is in fact a managerial, social concern under the influence of the so-called *flawed education across science and technology* and *misinterpretation of risk*. Three cases are described in the following to exemplify situations where techno-ethical risks arise:

First: Planning to replace a corporate legacy system by a web-based facility but concentrating on potential economic efficiency such as improved speed, elimination of redundancy or even reduced head-counts only, will miss such adverse consequences as deterioration in morale and end-user dissatisfaction (due to the disturbance to inertia).

Second: Evaluating information governance of a computer-based system but failing to include an audit of or a check for ethical issues will run the risk of a deficient information security management review.

Third: Assessing softlifting (the software equivalent of shoplifting) by focusing on the economic and legal impact such as infringement of copyright law and leaving out the social impact such as personal use of sensitive proprietary information will result in a risk of an incomplete assessment.

An Ideal Solution

As alluded earlier, an ideal solution is required to satisfy the hexa-dimension criteria, and is structured around, requisite competence and additive to supplement the requisite competence which alone is not sufficient.

REQUISITE COMPETENCE

Technical Know-How

Professional practitioners and layman users of IT presumably possess the basic rudiments. So this primary competence can be safely assumed.

The Basic Ethical Principles

IT professionals of various ranks, including CIOs, tend to offer support when asked for an opinion on the importance of computer ethics, but when pressed for elaboration as to what computer ethics is or why it is important, many may respond in silence. In order to proceed, we need a real appreciation of the basic ethical principles. To know what these theories are and how they can be used to explain the dilemmas, let us illustrate using the Edward Snowden episode. Was he a whistle-blower or simply a rumor-monger? Some respect him, calling him a hero; others disapprove of his actions, calling him a traitor. Is he defensible on ethical grounds? One might have heard of these arguments: “Snowden is not the only one. There are plenty other whistle-blowers,” or “If Tom, Dick and Harry can do it, why not Edward Snowden?” These arguments are based on the concept of relativism.

Relativism:

Right or wrong is not absolute, that is, what is right for you may not be right for me or I can decide to do what I think is right for me, but you can decide what is right for you.

Hence, if one person thinks it is right to say Snowden is a hero, but another individual does not think so, the argument is pointless, as it allows two people to decide right and wrong for themselves. In the end, no moral distinction between the opinions of the two individuals can be made. Certainly, the debate does not tell us whether Snowden’s actions are morally right or wrong.

Snowden is no ordinary worker; he is a professional, one who engages in a job that handles a highly sophisticated commodity—confidential information. He was an employee of the US National Security Agency (NSA). In this capacity, Snowden appears to be wrong, disloyal to his employer in stealing and disclosing confidential information without authority. However, while in the role of a professional, Snowden is expected

to respect professionalism and to observe his professional code of conduct, he has, as a person, a duty to himself and to his moral convictions. This duty-based argument is based on the theory of deontology.

Deontology:

An act is morally right if it is done out of a sense of duty.

So, as an employee, Snowden failed as he was disloyal and leaked confidential information. But, as a professional, he was right in exposing the stealth act because he was acting in accordance with professional conduct. While helpful in defending duty-bound actions, this principle is inherently troublesome because the actor owes responsibility to a multitude of stakeholders, and each of the stakeholders has its own aims that may be conflicting with one another.

Next, let us think of the impact or the consequences of Snowden’s actions. The consequences may be beneficial or harmful. Snowden might have done something “good” for the victims in particular and the world at large, and “bad” for NSA and the US government. This result-based argument, which is influenced by the concept known as consequentialism.

Consequentialism:

An action is morally right if its consequences are beneficial, and an action is morally wrong if its consequences are harmful.

The consequentialist argument is not sufficient and raises such questions as for whom or for how many is the result good, how good or how bad. This argument needs to be supplemented with a utilitarian view.

Utilitarianism:

An action is morally wrong if its harmful results are greater than its beneficial results, and all persons should pursue the greatest good for the greatest number of people.

A utilitarian argument may be useful to suggest the issue: for whom or what purpose the good result is beneficial or the bad result is harmful, but it raises further questions that include, among others, quantifying and comparing the results.

Besides these, others which are noteworthy are the Categorical Imperative and Social Contract Theory, and the so-called Golden/Silver Rule.

Kantian Categorical Imperative:

Never treat human beings merely as means to an end; always treat them as ends in themselves.

Social Contract Theory:

An action is morally wrong if someone's rights are being violated.

Golden Rule:

"Do unto others as you would have them do unto you" or "we should do to others what we would want others to do to us"; this is derived from "Do not do unto others what you would not have them do unto you" (sometimes referred as Silver Rule).

ADDITIVE

As can be seen, none of these principles alone can help to arrive at the ideal solution. To meet this end, a mix of some or all of these principles is necessary. Obvious, having the requisite knowledge is not enough, and something in addition is needed. That something, it is argued, comprises a new concept of risk, Ethical Risk, and a new tool for analysis of the dilemmas, Ethical Matrix (Lee, 2015a). This new view of Computer Ethics forms the core of the Ethical Movement in Cyberspace (Ethical Movement) (Lee, 2015b) advocated by the Computer Ethics Society (iEthics) (The Computer Ethics Society, 2012).

A New Concept of Risk

Connecting Security/Risk and Ethics

The human users of technology who create the risks, take them as *techno-economic risks* (due to *misinterpretation of risk* and the *flawed education*) (Lee, 2015a). It has been argued that abusing or not abusing the technology depends on the users' sense of morality which is influenced by many factors, amongst which is their understanding of the ethical principles. Using the technology in contradiction to ethical principles constitutes a different type of risk called *ethical risk vis-à-vis* risk of a technical, legal or financial nature, because it is a technical and managerial concern and should be measured in financial, legal and moral terms with equal priority.

For example, taking home from work a USB containing corporate data for personal convenience runs the risk of breaching the security for privacy or confidentiality. This is a situation where threat (t) exploits vulnerability (v), thus causing loss, damage or destruction to an asset (a), or $R = f(t, v, a)$. In this case, the person who takes home an un-encrypted USB in which confidential data are stored is a Threat, taking home an USB is a Vulnerability, and this action is a violation of data privacy, thus a risk.

This new risk is related partly to technology (the USB) and partly to people (both the perpetrator and the victims); it is therefore a risk of technological cum social nature in cyberspace, a new risk that can be called a *techno-ethical risk*, simply *ethical risk*. Figure 1 below depicts this phenomenon.

In cyberspace, as in the physical world, security relies on trust; trust depends on privacy; privacy is breached if law is not observed and if ethical principles are not followed. So, you would trust or disclose anything confidential to only those who respect privacy; you would trust your security in

Figure 1. Techno-ethical risk (connecting philosophy/technology)

Source: Lee, 2015d.

the protecting agent who would act according to ethical principles. Hence, trust will be lost or damaged, and undesirable consequences will follow if there is no privacy. Figure 2 is a sketch of the interrelationship of these entities.

Figure 3 combines the figures 1 and 2, and also shows the influence of law on privacy, and the link of techno-ethic risk to cybersecurity.

Shifting Our View of Risk

Security problems, be they of a technical or non-technical nature, is rooted in human mistakes to which none of us is immune. Wherever and whenever is there vulnerability, there is threat ready to exploit. Risk will result whenever a threat is actually carried out. To mitigate *risk* (that is,

Figure 2. Connecting security/risk and ethics

Source: Lee, 2015d.

Figure 3. Connecting philosophy/technology and ethics/(security/risk)
Source: Lee, 2015d.

the damage, loss or destruction of we what we want to protect), we must identify *threat* and deal with *vulnerability*. Obviously, risk is a function of vulnerability and threat, or $r = f(v, t)$, and exposure of risk is a function of probability (the likelihood that risk occurs) and damage (of technical, financial and ethical nature) or $R = f(p, d)$.

Computer Ethics, as advocated by the Computer Ethics Society, can be viewed as a double duality representing a dual mission: computer ethics as a practice and a discipline, and as a dual function: computer ethics playing the role of a different type of risk and an alternative category of (Lee, 2015a). The impact of knowledge of Computer Ethics on students' behaviour, as hypothesized by in a classroom study, empirically supports the anti-risk mechanism role of Computer Ethics (Lee and Chan, 2008). The double duality (Lee, 2014-15) is reproduced below, shown as Figure 4.

The support of the Lee-Chan hypothesis, which was deduced from the empirical data of investigating the effect of Computer Ethics in a Computer Science syllabus (Lee & Chan 2008), showing i) 62% of the students claimed that they

never heard nor aware of Computer Ethics and were not sure if they used the computer ethically before taking the course (Question ii response) and 72% understood Computer Ethics and would use the computer according to ethical principles after finishing the course (Question iv response), ii) a small percentage (4.5% - Question viii responses) of the students claimed that they were indifferent to or did not care about Computer Ethics (Question viii response), and iii) 2.5% (the union of Question vi and Question vii response) claimed that they would not change their view (Lee, 2015a). It should be of interest to note that the number of participants in the annual survey averages about 100 over the six years (2006 to 2012). It is also worthy of further investigation to ascertain of the 2.5% of students who claimed not to change their view, 1% is clearly anti-ethics, what view the 1.5% of the students (Question vi response) would adopt. On account of a typo discovered in the response rate (Question viii), which should be 4.5% and not 5.5%, the corrected Table 1 (Lee, 2015a) is reproduced.

Figure 4. Conceptual graph: double duality

Source: Lee, 2014-2015.

Table 1. Average response rates

Questions before Attending the Course	Rate
I heard or was aware of computer ethics, but I did not know if I used my computer ethically.	8%

A New Tool for Ethical Analysis

Ethical Matrix

Ethical Matrix, newly adopted by Ethical Computing as an additional approach to its tools and methods for performing ethical analyses (Lee, 2015a), poises to supplement the requisite competence. Checking for potential ethical and social impact (in addition to technical and economic efficiency) adds a step or steps to the other established anti-risk countermeasures. For example, going through the process of applying the Ethical Matrix method will force decision makers to

consider adverse consequences. This may reveal such risks as user morale and satisfaction or potentially undesirable consequences of a social or moral nature that would otherwise be missed in the typical anti-risk checks and audits, in addition to technical and economic efficiency issues such as improved speed, elimination of redundancy or reduced head counts. This makes computer ethics a different kind of anti-risk mechanism *vis-à-vis* the extant risk countermeasures including the following.

- Technical access control comprises physical and logical access controls such as

passwords, firewalls, intrusion prevention systems (IPS), secure web, email gateways, cryptographic algorithms and Anti-Virus Systems or Software (AVS). However, these mechanisms can handle only the physical, tangible errors or risks, but not risks of a sociotechnical nature.

- Computer law is useful as a reference framework for remedy and can be a forceful deterrent to prevent abusive acts by virtue of its power to punish. However, it is not as effective as expected: It is too slow to combat rapidly developed cybercrimes, and the process of creating new laws when needed is too complex and time consuming. Furthermore, people are, in general, reluctant to proceed with legal action or they opt for legal action only as a last resort.
- Risk analysis relies on the probability of occurrence and the associated damage or loss that the analyst estimates based on the threats identified and the related vulnerabilities in a risk assessment exercise. It is helpful in detecting risks but not very useful in preventing or powering them.
- Computer audit is useful for detecting deviation from set policies of performance and checking and verifying that compliance is properly enforced and results are consistent with the set standards, but in physical, cost-benefit terms only. The audit-based mechanism is, therefore, limited as a deterrent.

These extant countermeasures are being rendered impotent by such emerging applications and technologies as the Internet of Things (IoT), big data and cloud computing, all of which are complex and sophisticated, and by the ever-lurking perpetrators who are always ready to crack any new countermeasures soon after they are developed and released. Anti-risk is becoming more difficult. New anti-risk mechanisms are, therefore, called

for in order to strengthen the weakened existing mechanisms.

Illustration of Ethical Matrix

The Story

The story about an online monitoring system implemented by Libnaw, a high-tech facilities distributor, and the dilemmas that CIO faced thereof, is that described earlier in this article to exemplify a post-implementation problem. The dilemmas created and needed to be addressed include 'deviation from the firm's policy for acquisition approval (company policy), privacy invasion, staff being treated as a means, and staff morale (staff), corporate image damage (HRM), professionalism (CIO), duty (EVP). (Lee, 2014)

The Dilemma

The EVP's request worries the CIO.

First, managerial-technical functional conflict: The online surveillance capability in the hands of the EVP will become a *managerial control function*. This deviates from the originally approved purpose: to provide the help-desk staff with an online diagnosis and problem solving aid (*a technical support function*).

Second, management-staff interest conflict: Watching (by the EVP or someone from her office) over the users' screens without the users knowing it has the potential of breaching personal privacy in the work place. This certainly alarms both the staff (for fear of privacy invasion) and the firm (for concern over corporate image and personnel welfare).

Third, professional interest-contractual obligation conflict: Entertaining the EVP's request implies using the surveillance function for spying on the staff. This affects not only the CIO (with respect to professionalism and deontological obligations) but also the EVP (on her duty to protect the corporate image from possible damage), the

staff (about being exploited by one or more rotten apples) and the firm (about staff morale and company policy).

Analysis

The stakeholders identified are the firm, staff, EVP, and CIO, and the categories of ethical values considered relevant to the identified stakeholders' concern are well-being, autonomy and justice/fairness. The results of a first-cut analysis is shown in Table 2.

The next steps including modifying, deleting or adding, stakeholders and/or category of ethical values and the final steps including quantifying and comparing the concerns, and concluding are left for the interested readers to contemplate.

REMEDIAL ACTION: FROM CONCEPT TO PRACTICE

Scenario 1: Chuck's Dilemma: Contract Spec Fulfilled but Problem Unsolved

The Story

Alluded to earlier in the description of a post-contract problem, the story goes like this: Chuck is a senior project consultant working for A1 ASP, an application software provider. A1 signed a contract with Alwaays21, a fashion boutique in town, for the provision of a total system, and

Chuck was assigned to take full charge of the project. Reading through the system specification, Chuck was hit by a couple of loopholes which could cause intermittent logic errors in the update routine of the inventory control function. These errors, though rarely occur, could, if triggered, be vital to the time-critical fashion business. Chuck has to decide: Keep quiet or tell (the boss and/or the client).

Keep Quiet

Chuck is very tempted keep quiet about his finding since it is probably the most popular option. Also, relativism allows him to go the way he thinks is right. Keeping quiet can save him the trouble of confronting the boss and/or the client and avoid suffering a highly likely unpleasant reaction. But taking this option may be against his sense of duty, and worries him when thinking of the potential, unpleasant consequences.

Tell the Boss or the Client or Both

As an employee, Chuck knows that he is obliged to protect company property, to uphold company welfare, and to be loyal to the boss. As a professional, he should look after the client's welfare as well as that of the employer and other stakeholders. The Golden Rule tells Chuck to treat Alwaays21 as he would treat A1; Categorical Imperative advises Chuck to be fair to both parties. Chuck begins to incline to telling both the boss and the client. However, he hesitates as the issue of extra

Table 2. The first-cut results

Respect for Stakeholders	Well Being	Autonomy	Justice/Fairness
Firm	Personnel welfare, corporate image	Personnel protection	Staff morale
Staff	Personal privacy	Freedom of personal movement	Exploitation by minority
EVP	Job security	Firm's welfare	Entitlement of support resources
CIO	System utility	Professionalism	Distribution of computer resources

Source: Lee (2014).

cost pops up. The extra cost might incur as a result of increase in labour cost and resource for implementing the amended version. Who is to bear that extra cost? Has he got a case? It occurs to Chuck that a consequentialist argument would help.

Tell the Boss

When told, as Chuck expects, the boss is upset about the oversight (the flaw in the inventory control function design), and furious when the issue of extra cost is raised. The boss appears unwilling to bear the full cost.

Chuck makes these points on utilitarian grounds that the value associated with the potential damage to A1's reputation plus the cost of potential law suit and the ruin to the relationship with Alwaays21 or loss of its business will far exceed the extra cost, and this may also lead to serious morale issues, loss of customer trust including that of Alwaays21, damage to brand name, among others. In deontological terms, implementing a project knowingly with inherent weakness is an act of dishonesty, a violation of the company's code of conduct and a deviation from fair trade practice.

The boss's attitude seemed softened.

Tell the Client

Dolly appeared shocked upon learning the problem. She demanded to have the vulnerabilities dealt with thoroughly before implementation, or to withdraw the contract.

In response, Chuck argued that Alwaays21 should bear some or even equal responsibility: the contract was signed by both parties as a result of a mutually agreed feasibility study and a fully validated spec (on deontological grounds).

A1 doesn't have to reveal the problem voluntarily in the first place and just went on to implement according to the contract (in relativistic terms).

Further, the extra cost is negligible compared to the potential loss of business and the interrup-

tion to operation, etc. if the hidden errors pop up and the cost for amending and repairing in future if the system is implemented now according to the original design (a similar argument with the boss in consequentialist terms).

Now A1 has run the altruistic extra mile. This honest and ethical practice should be encouraged and praised, not rebuked and punished.

Closure

In the end, both A1 and Alwaays21 agree to amend the design and the contract, and to contribute equally to the extra cost.

Scenario 2: Taking Home a USB from Work

Taking home something like a biro from work is so common that it happens all the time, and probably nobody really cares about it. But taking home a USB is a different kettle of fish, and should not be taken lightly. People who do that unconsciously or for a purpose should realize that it is company property; it may contain proprietary data which may or may not have been encrypted; leaving where it belongs may be vulnerable to leaking (the content), physical damage to or loss of the device; and the potential liability to breach of privacy policy, thus incurring cost for law suit, and resulting in bad publicity, diminished trust, and so on.

The Story

One day in the early afternoon, Alex took with him a USB when he left office his (in Causeway Bay) in a hurry because he was trying to get to an evening seminar in Central in time and intended to continue working on his assigned project at home after the seminar. Alice accidentally spotted the act when passing Alex's office on her way to the staff pantry.

Complication

- Alex and Alice had been dating for almost two years and are getting steady.
- Betty (the boss) recommended to promote Alex only last week.
- The USB contains classified information, forbidden by company rules to leave company premises.
- The USB is not encrypted.

Dilemmas

- For Alice: report the case or not.
- For Alex: pretend to be ignorant of the rules or confess and defend on ground that though deviating from the rule, the intent of taking the USB away from office was to work at home, a contribution to increase in productivity.
- For Betty, the boss, when Alice reported Alex's act: to reprimand, to dismiss the report, or what?

Concerns

- Loyalty (Alex and Alice have for each other due to their intimate relationship, and for the company)
- Professionalism (Both Alex and Alice regard themselves as IT professionals)
- Alex's pending promotion (a concern shared by Betty, Alex, Alice and the team)

- Upholding company welfare, protecting company property
- Observing data privacy policy

Analysis

Obviously, there are four stakeholders: Alice, Alex, Betty and the team. The ethical values considered relevant to the identified stakeholders' concern are deontology, utilitarianism and consequentialism. The results of a first-cut analysis is shown in Table 3.

FUTURE RESEARCH DIRECTIONS

Ethical Matrix is a viable tool for ethical analysis of cyber-security issues. Application of this tool should be further developed and the first to develop is a quantification scheme for prioritizing remedial actions on the concerns, for only after a metric is developed and well validated can the concerns be compared and remedial actions taken. Interest in Computer Ethics is growing, though not as fast as expected; it must grow as cybercrimes grow; it needs time to accelerate as we take time to shift our view of risk (Lee, 2015c). Ethical Computing is to grow in importance in combating the constantly increase of ethical issues due to the alleged increase in hacking instances, insider perpetrators, security and privacy concerns associated with the emerging technology such as Big Data, Cloud Computing, and Internet of Things.

Table 3. The first-cut results: the USB case

Respect for Stakeholders	Deontology	Utilitarianism	Consequentialism
Alice	loyalty to Alex, company, professionalism	Alex's promotion	violation of data privacy policy
Alex	productivity	promotion	data protection
Betty	firm's welfare & property	her recommendation of Alex's promotion	data leaking
The team	team spirit & morale	promotion opportunity, fairness of treatment	data privacy

Source: Lee (2015d).

CONCLUSION

Many of the problems in the technology-driven information-intensive environment that could have been avoided or mitigated, occur because the ethical aspect of these problems is ignored or not recognized. It has been argued that solutions for these cyber-problems need to meet the six criteria: technical efficiency, financial viability, legal admissibility, social desirability, environmental sustainability, and ethical acceptability. It has been further argued that a deep understanding of the basic ethical principles, a shift in our view of ethics to include Ethical Risk, and a new tool for analysis of Ethical Risk (Ethical Matrix) are required. A completely ideal solution may not be readily and easily achieved. Some remedial action has been illustrated by means a few cases.

Computer Ethics that connects Technology (security and risk) and Philosophy (ethics and privacy). Ethical Computing as a practice that aims at establishing the ethical standards for guiding specialists and laymen alike through the ethical dilemmas are getting more important as a weapon against cyber-abuses that cause damage in excess of billions of US dollars. Further development is necessary and worthwhile.

KEY TERMS AND DEFINITIONS

Additive: This is a supplement to the requisite competence which alone is not sufficient, and a requirement of a change in viewing risk as having not only technical, physical, financial and legal but also ethical and social implications, and a tool or method to cater for this type of risk.

Computer Ethics: Applied Ethics referring ethical issues arising out of using the computer and its peripherals.

Ethical Computing: The practice of Computer Ethics and can be regarded as a branch of Computing, somewhat akin to Green Computing, Mobile Computing, and Cloud Computing. Whereas the others deal with tangible aspects of Computing, Ethical Computing handles techno-ethical aspects.

Ethical Risk (Short for Techno-Ethical Risk): Abusing technology or technology-based systems constitutes a risk called techno-ethical risk or ethical risk. Using the computer or developing computer-based systems or software inconsistent with ethical principles results in computer-ethical risk or simply ethical risk.

Hexa-Dimension Criteria: This refers to an ideal state expected of a solution that is technically efficient, financially viable, legally admissible, socially desirable, and ethically acceptable. Another dimension “environmentally sustainable” was added making a hexa-dimension model was developed and presented for consideration as a metric for the design of a code of conduct corporate-wide or functional unit based (Lee, 2015d).

Ideal Solution: To solve the problem which is required to satisfy the penta-dimensional criteria, the proposed solution is structured around the two major components, *requisite competence* and

additive (to supplement the requisite competence which alone is not sufficient).

Requisite Competence: This comprises the technical-know (the rudimentary skills and knowledge to use the computer) and a deep understanding of the basic ethical principles.

Technology-Driven Information-Intensive: This is a phenomenon that characterized the contemporary society and attributes to the vicious circle: increase in demand for information leads to increase in reliance on technology, and increase in use of technology consumes and generates more information. On the one hand, to capture market share and attract customers, contemporary business organizations rely increasingly on information technology to accumulate and process data needed to advertise services and products. Hence, the marketplace becomes more transparent, and the consumers are better-informed thus more demanding. More information is required and technology is more heavily relied upon. On the other hand, to aid business, to increase the processing power, and to handle the increase in data volume, new technological facilities such as call center and weblining (for marketing), and Big Data, Internet of Things, Cloud Computing (for communication and data management) are developed and used by business but these facilities consume and generate more data. In turn, reliance on technology increases to handle the information explosion.

The Basic Ethical Principles: For the purpose of this exposition, included are relativism, deontology, consequentialism and utilitarianism, categorical imperative, Social Contract Theory, and Golden Rule.

The Computer Ethics Society: Was established in 2012, aiming to promote professional and ethical standards, and to foster an open platform for sharing and interchanging experience and knowledge of moral issues associated with the use and development of ICT-based systems (www.iEthicsSoc.org).

The Problem: Referred to in this article: Its symptom is the phenomenon called technology-driven information-intensive. Its cause is techno-ethical risk or *ethical risk*. This type of risk created because the user not only is insensitive to or ignorant of the ethical aspect of the problems and its ramifications, attributing to a lack of deep ap-

preciation of the ethical principles, but also treats risk as a technical, corporate/personal matter when it is in fact a managerial, social concern under the influence of the so-called *flawed education across science and technology* and *misinterpretation of risk*. Post-contract problems and post-implementation problems are typical examples.

Group Signature System Using Multivariate Asymmetric Cryptography

Sattar J. Aboud

University of Bedfordshire, UK

INTRODUCTION

The group signature lets the group of people to sign document anonymously on behalf of other group. In the case of the dispute, the designated director can open the signature to disclose the identity of its generator. To the degree that we know the majority of the group signatures are relied on the known schemes, such as RSA and ElGamal. However, these schemes could be broken when quantum computers appear. The problem typed multivariate asymmetric key cryptography is the notable option to common asymmetric schemes for its possible to withstand future attacks of quantum computers. The initial group signature scheme relied on the multivariate asymmetric cryptography that is introduced in this chapter. The proposed scheme have two extraordinary attributes. In the first one, the group signatures are divided to dissimilar time intervals. The signatures are linkable in the same time interval, but un-linkable among dissimilar time intervals. In the second one, the duties of the group director is restricted. The group director does not allow him to open the signature without the assist from the verifier. These attributes are vital in selected uses such as e-voting schemes. The concept of the proposed scheme is straightforward and its security bases on both an arbitrary hash function and an isomorphism of polynomial problem.

In 1991, Chaum-Heyst presented the first idea of group signature. The group signature scheme give permission to the group of people to sign the documents on behalf of the group. The verifier can only inform that the signature is signed by the person from the group, but cannot determine

the identity of the signer. In addition, the verifier cannot differentiate if the two signatures are published by the same person of the group. But, in special case such as official dispute, the designated group director can open the signature to disclose the identity of its generator. At the same time, no one even the group director can forge the signature of other group people.

The characteristics of group signature construct it smart for many specific applications, like e-voting, e-cash and e-games. For instance, in e-voting systems, the electorate are not allowable to vote many times. Thus the count authority should be capable to differentiate the reduplicate votes without opening an election. Furthermore, there is a rule exist supervision authority to constraint the duties of the count authority and promise the fairness of the voting in the voting system. Thus, the group signature schemes cannot be employed the e-voting systems straight. Most of the group signatures are using known cryptography schemes, such as RSA and ElGamal. However, the algorithm proposed by Shor illustrates that solving the factoring integers and the discrete logarithms can be achieved in polynomial time on the quantum computer. If the quantum computers become a reality, the common asymmetric key cryptography under these problem, such as RSA and Elliptic curve will be broken. multivariate asymmetric key cryptography is studied to be one of the best option. The security basis of multivariate asymmetric key cryptography is the information that solving the set of multivariate polynomial formulas over the finite field is the NP-hard problem. Quantum computers do not seem to have any benefit if managing this NP-hard problems, and

DOI: 10.4018/978-1-5225-2255-3.ch424

it appears that we cannot recover the solution to the set of polynomial formulas efficiently even in the future. Furthermore, multivariate asymmetric key cryptography schemes are more efficient than common asymmetric key cryptography. It makes them appropriate for restricted computing tools, for example smart cards. Different multivariate asymmetric key cryptography schemes have been presented.

QUANTUM COMPUTING THREATENS

Quantum computing threatens definite techniques and does not threaten others. Public key encryption, is being used considerably for securing the internet payments, banking transactions, and also emails and webs. The majority of today cryptography schemes are using public-key cryptography, that is in fact secure anti-attacks from contemporary computers.

Suppose that quantum cryptography can easily break many schemes by inverse the computing private-keys and quicker than the classical computer. While quantum cryptography are still in their early stages and non-equipped, with publicly known new quantum computers, small to attack traditional cryptography algorithms, many public authorities have begun to know the risk included if this technology becomes the practical applications. Since quantum computers is to process huge amounts of information in the quite short of time.

Traditional cryptography schemes provide computational security but is not ensure perfect or resistant security. The power of the existing cryptography algorithms based on composite mathematical problems, for example integer factoring, elliptic curve and discrete logarithm problem. Such difficulties can deciphered by applying large-scale quantum cryptography and thus can simply break traditional schemes. Consequently, experts have started planning new encryption schemes that are considered quantum-resistant that cannot be broken as fast as traditional algorithms.

The National Security Agency recognized the quantum processing threat by publicly announcing their strategies for changing to quantum unbreakable methods. However, the quantum processing threat has increased over public key infrastructure that is applied greatly in protecting the webs.

Quantum cryptography can be attack both symmetric schemes such as block ciphers, and asymmetric schemes such as RSA and DSA. Such cryptography can break each single public key algorithm in the small amounts of time. Quantum methods, for example Shor scheme, can be applied to retrieve the RSA key in polynomial time, but quantum cryptography with sufficient power at present is not existed.

Post-quantum encryption is being utilized for designing cryptography methods that are believed to be secure anti-attack by quantum processors. It is expected that 2048-bit RSA keys can be defeated on the quantum computer containing 4000 qubits and 100 million gates. Even if there are some public-key methods that are believed resistant, they are not utilized currently, since Quantum algorithms is based on difficult and complicated mathematical problems to give security that is stronger than conventional cryptography. If quantum cryptography becomes the truth, it will product in re-engineering and improvements in existing encryption schemes.

BACKGROUND

Due to its significant attributes, group signature draw many authors attentions. However, in addition to the first scheme proposed by Chaum-Heyst, there are many other schemes appear. For example, Chen-Pedersen in 1994 presented the new group signature scheme which conceal an identity of the signer categorically and permitted new persons to associate the group. Also, in 1997 Camenish-Stadler introduced an efficient group signature scheme for large groups, with the size of public keys and the size of signatures are free of the group persons. In

2000, Ateniese *et al.* presented the group signature scheme relied on other number theory topics with good efficiency and robust security. In 2003 Chen-Yang proposed another digital signature scheme called TTS/4. It is from the family of multivariate cryptography schemes. They claim that TTS/4 is competitive and better compare with other schemes. In 2004, Ding introduced the new variant scheme from the concept of perturbation. This scheme employs the set of small number linearly independent functions. The difference between the proposed thought and the similar concept of the concealed field equation and Oil-Vinegar scheme is that perturbation is internal, while other schemes are external perturbation. In 2010, Petzoldt, *et al.* they extend the thought of the Rainbow signature scheme. They claim that the construction of their scheme able to decrease the length of the public-key up to 62%. In 2011, Jintai Ding published a patent contains three schemes to construct new multivariate public-key schemes that are better in security and efficiency. The three schemes are entitled the internal perturbation plus, the enhanced internal perturbation and the multi-layer Oil-Vinegar construction. In 2012, Noaki Ogura, proposed scheme concerning the multivariate public-key scheme. In 2014, Ning Huang analyzed and solved the errors of the medium field multivariate public-key encryption scheme.

In the multivariate asymmetric-key cryptography schemes, the asymmetric-key is the set of polynomials $p = (p_1, \dots, p_m)$ in integers $x = (x_1, \dots, x_n)$, with all parameters and coefficients are in $K = GF(k)$. This is typically achieved by:

$$P = S \circ Q \circ T : K^n \rightarrow K^m$$

or

$$\begin{aligned} P : w = (w_1, \dots, w_n) \in K^n &\xrightarrow{T} x = M_T w + c_T \\ &\xrightarrow{Q} y = M_S y + c_S = (z_1, \dots, z_m) \in K^m \end{aligned}$$

The central map Q be owned by the certain class of quadratic maps whose inverse does calculated straightforwardly. The maps S and T are affine and bijective. The private-key contain the central map Q and affine maps S, T .

MAIN FOCUS OF THE CHAPTER

In this section, we are going to describe the contribution, then the traditional schemes, the solution scheme, then the discussions and finally the conclusions and remarks.

The Contribution

This Chapter presents a new group signature scheme using multivariate asymmetric cryptography. Compared with the existed signature schemes, The proposed scheme is applicable to e-voting schemes and can convince the requirements of e-voting schemes because it has two important characteristics, Traceability and Unlinkability. Traceability denotes that a group director cannot open the signature alone. He has to collaborate with a verifier to disclose an identity of the signer. Unlinkability denotes that the group signature can be split accordance to time durations. Then signatures are linkable in the same time range, but un-linkable between dissimilar time periods. Therefore, the count authority can notice the double-votes prior to open them. Thus, there are two features in the proposed signature, for count and supervision authority. Also, the size of signatures and the calculation overhead are private from the group members in the proposed scheme. So, it is efficient for large groups.

The Proposed Group Signature Scheme

The customary group signature schemes permit the user to sign documents anonymously on the behalf of his group. The verifier can check that the signature was signed by the user of the group,

nevertheless cannot determine which user of the group signed it. Also, the signatures are unlinkable, which means that provided two group signatures, the verifier cannot distinguish if they are published by the same group user or not. However, the unlinkability seems not modified to some uses for example the e-voting schemes. The verifier must be capable to differentiate the over-votes, in the meantime the anonymity must be certain. In addition, in customary group signatures the group director can open any group signature randomly.

Although in the e-voting schemes, there is typically the supervision organization to assure the fairness of the voting. Thus we want to constraint the duties of the group director. Thus, the customary group signatures cannot be useful with e-voting schemes straight. In order to solve these difficulties, we introduce the new group signature scheme fitted with e-voting schemes. The proposed scheme is described as follows.

1. **Unlinkability:** The group signature is divided into time duration. The signatures in the same time range are linkable. The verifier can check if two signatures are published by a same group member. But the signatures between dissimilar time period are unlinkable. They are entirely anonymous. This property is useful in the e-voting schemes. For instance, in the voting there are numerous positions require to be chosen. Every duration for one position. As the votes in the same period are linkable, the verifier is capable to differentiate the over-votes without opening them. All at once, the ballots between dissimilar ranges are un-linkable, thus ballots for diverse position are anonymous.
2. **Traceability:** The group director and the verifier cannot disclose an identity of the signature individually, but they can do it jointly.
3. **Correctness:** The group signature published by a valid group entity and should be accepted by a verifier.

4. **Unforgeability:** Only the legitimate group entities are capable to sign documents on behalf of the group.
5. **Undeniable:** Both the group entity and the group director is capable to sign documents on behalf of other group entities. This also causes the group signature undeniable.
6. **Anonymity:** Provided the legitimate group signature, no entity can disclose the identity of a real signer, unless the group director opens the signature with an assist of the verifier.

In the proposed scheme, the group director cannot open the signature randomly. His duties is restricted. This characteristic is significant in some application such as the e-voting schemes. The management usually contains the count authority and the supervision authority. Neither of them can disclose an identity of the vote alone. They have to act jointly to open the vote to disclose a real identity. This characteristic lets the voting more open.

Signature of Knowledge

In this section, we present the signature of knowledge using multivariate asymmetric key cryptography, which is the construction block of the proposed scheme.

Isomorphism of Polynomials Problem

The isomorphism of polynomials problem was first presented by Patarin in 1996. It is the basic problem of multivariate encryption because it is connected with the difficulty of the key recovery of the schemes. The idea of Isomorphism of Polynomials is illustrated as follows.

Suppose that $K = GF(k)$ is the finite field. All parameters are over the field K . Assume that A are the set of u quadratic formulas with n parameters $x_1, \dots, x_n$ that provide y values from x values:

$$y_k = \sum_i \sum_j Y_{ijk} x_i x_j + \sum_i u_{ik} x_i + \delta_k \quad \text{where } k = 1, \dots, u$$

Given B is the set of u quadratic formulas with n parameters $x'_1, \dots, x'_n$ that provide y' values from x' values:

$$y'_k = \sum_i \sum_j Y'_{ijk} x'_i x'_j + \sum_i u'_{ik} x'_i + \delta'_k \quad \text{where } k = 1, \dots, u$$

Suppose that T is the bijective affine transformation of the parameters x'_i where $1 \leq i \leq n$ with S is the bijective affine transformation of the parameters y_k , such that $1 \leq k \leq u$. Then

$$T(x'_1, \dots, x'_n) = (x_1, \dots, x_n) \\ S(y_1, \dots, y_u) = (y'_1, \dots, y'_u)$$

When there is the transformation pair (S, T) to convince $B = S \circ A \circ T$, we said to be A and B are isomorphic, and the bijective affine transformation pair (S, T) is the isomorphism from $(A$ to $B)$. When A and B are two public sets of u quadratic formulas, and A and B are isomorphic, get isomorphism (S, T) from $(A$ to $B)$.

Signature of Knowledge Protocol

Zero-knowledge proofs permit the prover to show the knowledge of the secret, without disclose any important information. Patarin introduced the non-interactive zero-knowledge proofs of knowledge scheme using an isomorphism of polynomial problem [13]. In this Chapter, we will use the simplicity but practical scheme we entitled it signature of knowledge which is as follows.

Assume K is the finite field. Given n, u, q are three variables, and H is the secure hash function $H : (0, 1)^* \rightarrow (0, 1)^q$ that maps the binary bits of random size to q -bit hash value. Assume A and B are two sets of u quadratic formulas with n parameters as follows:

$$A : y_k = \sum_i \sum_j Y_{ijk} x_i x_j + \sum_i u_{ik} x_i + \delta_k$$

where $k = 1, \dots, u$

$$B : y'_k = \sum_i \sum_j Y'_{ijk} x'_i x'_j + \sum_i u'_{ik} x'_i + \delta'_k$$

where $k = 1, \dots, u$

Suppose m is a document to be signed. Request $q + 1$ parameters $V = h, (S_1, T_1), \dots, (S_q, T_q)$ the signature of knowledge involved (A, B) and document m , when the following conditions are convinced: $C_i = S_i \circ A \circ T_i$, if $h(i) = 0$ or $C_i = S_i \circ B \circ T_i$, if $h(i) = 1$ with $1 \leq i \leq q$, and $h = H(m \parallel C_1 \parallel C_2 \parallel \dots \parallel C_q)$.

When a prover identifies the isomorphism (S, T) from $(A$ to $B)$ means $B = S \circ A \circ T$, then a signature of knowledge can be created as follows.

The prover chooses q arbitrary bijective affine transformation pairs $(S'_1, T'_1), \dots, (S'_q, T'_q)$ which appear like:

$$T'_1(x_1^{(1)}, \dots, x_n^{(1)}) = (x_1, \dots, x_n), S'_1(y_1, \dots, y_u) = (y_1^{(1)}, \dots, y_u^{(1)}) \\ T'_q(x_1^{(q)}, \dots, x_n^{(q)}) = (x_1, \dots, x_n), S'_q(y_1, \dots, y_u) = (y_1^{(q)}, \dots, y_u^{(q)})$$

The prover finds:

$$C_1 = S'_1 \circ A \circ T'_1 \\ C_2 = S'_2 \circ A \circ T'_2 \\ : \\ C_q = S'_q \circ A \circ T'_q$$

Then, gets q sets of u quadratic formulas with n parameters as follows:

$$y_k^{(1)} = \sum_i \sum_j Y_{ijk}^{(1)} x_i^{(1)} x_j^{(1)} + \sum_i u_{ik}^{(1)} x_i^{(1)} + \delta_k^{(1)}$$

where $k = 1, \dots, u$

$$y_k^{(q)} = \sum_i \sum_j Y_{ijk}^{(q)} x_i^{(q)} x_j^{(q)} + \sum_i u_{ik}^{(q)} x_i^{(q)} + \delta_k^{(q)}$$

where $k = 1, \dots, u$

The prover finds a hash outcome $h = H(m \parallel C_1 \parallel C_2 \parallel \dots \parallel C_q)$. Assume that the binary format of result h is introduced as $h(q) \dots h(2)h(1) \in (0,1)^q$. The prover finds $(S_i, T_i) = (S'_i, T'_i)$, if $h(i) = 0$, or $(S'_i \circ S^{-1}, T'^{-1} \circ T'_i)$ if $h(i) = 1$ where $1 \leq i \leq q$. Therefore, the signature of knowledge V is built.

If the verifier receives the public key (A, B) , the document m , and the signature of knowledge V , the steps of the signature verification is as follows.

The verifier finds q sets of u quadratic formula by

$$C_i = S_i \circ A \circ T_i, \text{ if } h(i) = 0 \text{ or } C_i = S_i \circ B \circ T_i, \text{ if } h(i) = 1 \text{ where } 1 \leq i \leq q$$

The verifier finds the hash value $h = H(m \parallel C_1 \parallel C_2 \parallel \dots \parallel C_q)$, and verifies if the new hash value h' is equal to h .

The Description of the Proposed Scheme

In this section, we introduce the new group signature scheme using multivariate asymmetric key cryptography, deal with the e-voting schemes.

Scheme Initialization

The group director setup the scheme parameters as follows:

1. Suppose that n, u, q are three integers. Also, let $K = GF(k)$ is the finite field.
2. H is the secure hash function $H : (0,1)^* \rightarrow (0,1)^q$ that maps the binary bits of random size to q -bit hash value.

3. Q is the central map chosen by a group director.
4. Every entity i has a secret key $(L_{1,i}, L_{2,i})$, and a public key $A_i = L_{1,i} \circ Q \circ L_{2,i}$.

Joining Group

Each user wants to join the group to get the ability of signing on behalf of the group. Assume that the user i needs to join the group.

1. User i chooses arbitrary bijective affine transformation pair (S_i, T_i) and maps A_i to B_i by $B_i = S_i \circ A_i \circ T_i$. The, A_i and B_i are isomorphic and affine transformation (S_i, T_i) is an isomorphism from $(A_i$ to $B_i)$. This pair (A_i, B_i) is the public key of user i in the group, while (S_i, T_i) is the secret key of user i in the group.
2. User i makes the signature of knowledge of (A_i, B_i) , represented by V_i , and passes the knowledge V_i and (A_i, B_i) to the group director. In this case, the interaction between a user i and a group director must be secure.
3. The group director checks the signature of knowledge. If it is true, he stores the knowledge V_i and (A_i, B_i) . if not, he erases the knowledge V_i and (A_i, B_i) , and reject the user i request.

Signing Documents

The group director can split the group signature to a number of time periods. The amendment of the period is ruled by the group director. So as to alter the period, the group director should do the following two phases.

First Phase: Change Period

The steps of this phase are as follows:

1. The group director chooses the public keys of various group users. These users form the sign group.
2. For each public key (A_i, B_i) in a sign group, the director makes the arbitrary bijective affine transformation pair $(S_{1,i}, T_{1,i})$, and finds

$$\begin{aligned} A_i^{(1)} &= S_{1,i} \circ A_i \circ T_{1,i} \\ B_i^{(1)} &= S_{1,i} \circ B_i \circ T_{1,i} \end{aligned}$$

The group director issued $(A_i^{(1)}, B_i^{(1)})$ to the bill-board. Then he posts each affine transformation pair $(S_{1,i}, T_{1,i})$ to the related user i in the sign group by a secure communication.

Second Phase: Signing

Inside every period, group users in the sign group can sign any documents on the behalf of the group, where the signatures are linkable. Assume that group user i needs to sign the document m , entity should perform the second phase as follows. The steps of this phase are as follows:

1. The user i passes $(A_i^{(1)}, B_i^{(1)})$ to verifier v .
2. The verifier v verifies that if $(A_i^{(1)}, B_i^{(1)})$ is in the bill-board. If yes, he chooses the arbitrary bijective affine transformation pair $(S_{2,i}, T_{2,i})$ and posts it to user i . Then he finds $A_i^{(2)} = (S_{2,i} \circ A_i^{(1)} \circ T_{2,i}, B_i^{(2)} = S_{2,i} \circ B_i^{(1)} \circ T_{2,i})$ and stores $(A_i^{(2)}, B_i^{(2)})$ and $(S_{2,i}, T_{2,i})$ in the database.
3. The user i finds $(A_i^{(2)}, B_i^{(2)})$. Then, he calculates the isomorphism (A'_i, B'_i) from $A_i^{(2)}$ to $B_i^{(2)}$ by:

$$\begin{aligned} S'_i &= (S_{2,i} \circ S_{1,i}) \circ S_i \circ (S_{2,i} \circ S_{1,i})^{-1} \\ T'_i &= (T_{1,i} \circ T_{2,i})^{-1} \circ T_i \circ (T_{1,i} \end{aligned}$$

With (S'_i, T'_i) user i can produce the signature of knowledge of document m and $(A_i^{(2)}, B_i^{(2)})$ indicated by $V_i^{(2)}$. Therefore $[V_i^{(2)}, (A_i^{(2)}, B_i^{(2)})]$ is the group signature published by user i .

Verifying Signatures

Upon receiving the group signature $[V_i^{(2)}, (A_i^{(2)}, B_i^{(2)})]$, a verifier v verifies the validity of the signature by two steps.

1. The verifier v decrypts the $(A_i^{(1)}, B_i^{(1)})$ by

$$\begin{aligned} A_i^{(1)} &= S_{2,i}^{-1} \circ A_i^{(2)} \circ T_{2,i}^{-1} \\ B_i^{(1)} &= S_{2,i}^{-1} \circ B_i^{(2)} \circ T_{2,i}^{-1} \end{aligned}$$

Then he verifies $(A_i^{(1)}, B_i^{(1)})$ if it is in the bill-board. If yes, he moves to the next step. If not the signature is invalid.

2. The verifier v verifies if $V_i^{(2)}$ is the valid signature of knowledge of document m and $(A_i^{(2)}, B_i^{(2)})$. If yes, he accepts the signature. If not the signature is invalid.

Linking Signatures

Suppose that the two group signatures $[V_i^{(2)}, (A_i^{(2)}, B_i^{(2)})]$ and $[V_j^{(2)}, (A_j^{(2)}, B_j^{(2)})]$. So, to check the double-signature is easy.

1. The verifier verifies if $(A_i^{(2)}, B_i^{(2)}) = (A_j^{(2)}, B_j^{(2)})$ then the two signatures are published by the same user. If not move to the next step.
2. The verifier decrypts the $(A_i^{(1)}, B_i^{(1)})$ and the $(A_j^{(1)}, B_j^{(1)})$ as follows:

$$(A_i^{(1)}, B_i^{(1)}) = (S_{2,i}^{-1} \circ A_i^{(2)} \circ T_{2,i}^{-1}, S_{2,i}^{-1} \circ B_i^{(2)} \circ T_{2,i}^{-1})$$

$$(A_j^{(1)}, B_j^{(1)}) = (S_{2,j}^{-1} \circ A_j^{(2)} \circ T_{2,j}^{-1}, S_{2,j}^{-1} \circ B_j^{(2)} \circ T_{2,j}^{-1})$$

If $(A_i^{(1)}, B_i^{(1)})$ and $(A_j^{(2)}, B_j^{(2)})$ are still dissimilar then the two signatures are published by unlike group users. If not, they are published by the same user.

- **Remark:** When the two signatures are from dissimilar periods, they are un-linkable. It means that the outcome of the Link operation is published by dissimilar group users.

Opening Signatures

To open the group signature to disclose the real identity of the signer, the group director has to assist with a verifier. For instance, $[V_i^{(2)}, (A_i^{(2)}, B_i^{(2)})]$ the group director receives the affine transformation pair $(S_{2,i}, T_{2,i})$ from the verifier. Then the group director finds (A_i, B_i) using $(S_{2,i}, T_{2,i})$.

$$A_i = (S_{2,i} \circ S_{1,i})^{-1} \circ A_i^{(2)} \circ (T_{1,i} \circ T_{2,i})^{-1}$$

$$B_i = (S_{2,i} \circ S_{1,i})^{-1} \circ B_i^{(2)} \circ (T_{1,i} \circ T_{2,i})^{-1}$$

The isomorphism from $(A_i^{(2)}, B_i^{(2)})$ to (A_i, B_i) is $((S_{2,i} \circ S_{1,i})^{-1}, (T_{1,i} \circ T_{2,i})^{-1})$. Therefore the group director obtains an identity of the real signer.

Security of the Proposed Scheme

The proposed scheme properties are as follows.

- **Unlinkability:** The signatures are linkable in the same time period, but un-linkable in dissimilar time periods.

Proof: In one period, group user j can obtain only one license (S_1, T_1) from the group director.

Therefore he can only generate one $(A_j^{(1)}, B_j^{(1)})$. He can inquire a verifier twice for (S_2, T_2) and (S'_2, T'_2) then generates $(A_j^{(2)}, B_j^{(2)})$ and $(A_j'^{(2)}, B_j'^{(2)})$ but a verifier will decrypt the same $(A_j^{(1)}, B_j^{(1)})$ using (S_2, T_2) and (S'_2, T'_2) respectively. Thus the signatures in the same time period are linkable. Whereas in dissimilar periods, the user j will obtain dissimilar licenses (S_1, T_1) and (S'_1, T'_1) from group director, and he generates $(A_j^{(1)}, B_j^{(1)})$. The verifier can decrypt them using (S_2, T_2) and (S'_2, T'_2) but he cannot decrypt the origin (A_j, B_j) . Thus, the signatures between dissimilar time periods are unlikable.

- **Traceability:** Both the group director and the verifier cannot disclose an identity of the signature alone, but they can disclose it jointly.

Proof: In the proposed scheme, after the computing of $(A_i^{(1)}, B_i^{(1)})$ the signer i maps the $(A_i^{(1)}, B_i^{(1)})$ to $(A_i^{(2)}, B_i^{(2)})$ by using an affine transformation pair $(S_{2,i}, T_{2,i})$ provided by a verifier. So, the group director cannot sets up the relationship between $(A_i^{(2)}, B_i^{(2)})$ and $(A_i^{(1)}, B_i^{(1)})$ without $(S_{2,i}, T_{2,i})$. Thus, the group director cannot disclose an identity of the signature. Also, a verifier cannot sets up the relationship between $(A_i^{(1)}, B_i^{(1)})$ and original (A_1, B_1) . Thus, the verifier cannot open the signature alone, unless otherwise there is a cooperation between the group director and the verifier to decrypt the identity of the signature.

- **Correctness:** The group signature published by a valid group user should be accepted by a verifier. where u is the polynomial numbers in Q , n is the parameter numbers.
- **Unforgeability:** The group user is capable to sign documents on behalf of the group.

Table 1. The best algorithms for isomorphism of polynomials

Problem	Sub-Case	Complexity
Isomorphism of Polynomials	degree = 2, $u = n$, inhomogeneous	$O(n^3) / O(n^6)$
	degree = 2, $u = n$, homogeneous	$O(n^{3.5} \cdot q^{n/2})$

Proof: The verifier can verify the public keys in the bill-board. Thus, to obtain the transformation pair $(S_{2,i}, T_{2,i})$ from verifier and produce the signature, the user i has to obtain the qualification from the group director.

- **Undeniable:** Both the group user and the group director are not capable to sign the documents on behalf of other group users.

Proof: Assume that the group user j needs to sign documents on the behalf of a group user i . The user j can inquire the group director for the affine transformation pair (S_1, T_1) and inquire a verifier for an affine transformation pair (S_2, T_2) . Then he finds $(A_i^{(2)}, B_i^{(2)})$:

$$\begin{aligned} A_i^{(2)} &= S_2 \circ S_1 \circ A_i \circ T_1 \circ T_2 \\ B_i^{(2)} &= S_2 \circ S_1 \circ B_i \circ T_1 \circ T_2 \end{aligned}$$

To produce the signature of knowledge $(A_i^{(2)}, B_i^{(2)})$ he must discover the isomorphism from $(A_i^{(2)}$ to $B_i^{(2)})$. It means that he must resolve the isomorphism of polynomial problem. It is arithmetically difficult without the secret key (S_i, T_i) of user i .

- **Anonymity:** Provided the valid group signature, no one can disclose an identity of the real signer, unless the group director opens the signature with an assist of the verifier.

Proof: Provided the group signature $[V_i^{(2)}, (A_i^{(2)}, B_i^{(2)})]$, to disclose an identity of the

signer, a hacker has to discover the affine transformation pair (S'_i, T'_i) that maps (A_i, B_i) to $(A_i^{(2)}, B_i^{(2)})$. This means that he has to resolve an isomorphism of polynomial problem. It is arithmetically difficult without $(S_{1,i}, T_{1,i})$, and $(S_{2,i}, T_{2,i})$ which hold by the group director and the verifier respectively.

COMPARISONS

We compare the proposed scheme with some other group signature schemes. The proposed scheme is the group signature scheme using multivariate asymmetric key cryptography, and is possible the first group signature scheme that withstands the future attacks of quantum computers. Thus, we can only compare the proposed scheme with the schemes using conventional cryptography. The early proposed group signature schemes are impractical for large groups, as the size of signatures. In the proposed scheme, the calculation of the operations are based on the number of group users. The size of signatures and the size of user keys are determined. But the size of keys of group director are linear in the number of group users, thus decreasing the storage space of the scheme can be part of the future work. But, this scheme is efficient for large groups. Also, compared with other schemes, the proposed scheme can be used in e-voting schemes directly because of two unique characteristics, the linkability and the traceability. Table 2 shows the comparisons between dissimilar group signatures.

Table 2. The comparisons between dissimilar group signatures

Characteristic	Chaum [1]	Petersen [25]	Ateniese [5]	Proposed Scheme
Cryptography Assumption	Discrete Log	Discrete Log	RSA and Diffie-Hellman	Isomorphism of Polynomial
Quantum Attack	Yes	Yes	Yes	No
Sign	$O(n)$	$O(n)$	Constant	Constant
Verify	$O(n)$	$O(n)$	Constant	Constant
Open	$O(n)$	$O(n)$	Constant	Constant
Size of Signature	$O(n)$	$O(n)$	Constant	Constant
Size of Key	$O(n)$	Constant	Constant	Director: $O(n)$ User: Constant

FUTURE RESEARCH DIRECTIONS

In the future work, we will consider conditions that undertaking an attack of Faugere and Spaenlehaner versus Akiyama *et al.* to make it works better. Also, we can produce keys that are more arbitrary than the keys of Faugere and Spaenlehaner applied then we can proved the effectiveness of their attack by our tests. In their attack we can infer data of the divisor polynomial f by finding the resulting of selected polynomials according to the encrypted document. Then, we can examine the scheme by using the theory of Gröbner basis computation.

However, we can introduced another multivariate public-key system by applying wild automorphisms, which are deeply examines in affine algebraic geometry. However, we create the private key as selected polynomial functions created by ρ – derivations, and announce the composition of such functions. As, we employ polynomial functions which ranges are high, the length of keys and the time complexity of scheme tend to be considerable. Thus, we have to decrease the key length and the time complexity.

CONCLUSION

This Chapter presents the group signature scheme under multivariate asymmetric key cryptography. Its security based on the isomorphism of polynomial problem and the secure hash function. Compared with other group signature schemes, the proposed scheme is design to e-voting schemes. Because of two characteristics, the unlinkability and the traceability, the proposed scheme can convince the additional requirements of the e-voting schemes. Also, the size of signatures and a calculation overhead are regardless of the number of group users. It is efficient for large groups.

KEY TERMS AND DEFINITIONS

Cryptography: Is the science and study of secret writing.

Hacker: Is a term used by some to mean a clever programmer and by other, especially those in popular media to mean someone who tries to break into computer systems.

Group Signature Scheme: Is a method for allowing a member of a group to anonymously sign a message on behalf of the group.

Multivariate Cryptography: Is the generic term for asymmetric cryptography based on multivariate polynomials over finite fields. Solving systems of multivariate polynomial equations is proven to be NP-hard. Today multivariate quadratics can be used only to build signatures.

Quantum Computers: Is the direct use of quantum-mechanical phenomena, to perform operations on data. Quantum computers are different from digital computers based on transistors. Whereas digital computers require data to be encoded into binary digits (bits), quantum computation uses quantum bits which can be in super positions of states.

Isomorphism of Polynomials Problem: Is a well-known problem studied in multivariate cryptography. It is related to the hardness of the key recovery of some cryptosystems.

NP-Hard Problems: Is a class of problems that are, at least as hard as the hardest problems in NP. More precisely, a problem H is NP-hard when every problem L in NP can be reduced in polynomial time.

Hexa-Dimension Code of Practice for Data Privacy Protection

Wanbil William Lee

Wanbil & Associates, Hong Kong

INTRODUCTION

Contemporary cyberspace inhabitants live and work in a *technology-driven information-intensive* era, a *phenomenon* born out of a *vicious circle*. The consequence is a mixture of blessing and nightmare. Data protection emerges as a critical concern and data privacy protection an urgent and vital problem for information security management. Given the situation, the front-line information security personnel is among the first to bear the brunt and in dire need of a pragmatic guidance.

A recently developed set of International Data Privacy Principles was proposed as a reference considered to be useful for tackling the *first need* (Zankl, 2016). Hong Kong's Personal Data (Personal) Privacy Ordinance (PDPO), a data protection principle-based law like many others legislated by western jurisdictions, which has been in force for a number of years (Chang, 2016), can make a contribution the *second need*. To address the *third need*, a framework that comprises a 6-d code based on the 6-d metric and an operationalization scheme is recommended.

A first-cut version of the framework was recently presented to an audience of Information Security Management specialists (Lee, 2015a). The rationale of the metric, the definition of the code and its worthiness for recommendation, and an indicative guideline to operationalize the code, are described in this article.

BACKGROUND

Technology-Driven Information-Intensive Phenomenon and the Vicious Circle

Netizens are provided with such technologies as *Customer Relationship Management*, *Web-lining* and *Call Centre*, and so on; they can by means of these facilities conduct their daily activities more efficiently and effectively, and optimize the outcome of these activities, because they are better-informed and able to innovate marketing, to accelerate business promotion, to enlarge data storage capacity and communication coverage, to increase retrieval facilities, and to improve transaction speed in a more transparent and open environment. But then they will need to rely increasingly heavily on the technologies. While transparency and communication keep on improving, more and more data are consumed and correspondingly generated. Briefly, "the happier the consumers of information, the higher the demand for more information and the more the technology is used, the more the data and the speedier the processing, the more transparent the cyberspace, and the happier the consumers" – a *vicious circle* is formed; the *technology-driven information-intensive phenomenon* created. (See Figure 1).

The consequence is good and bad. The good is the accelerated arrival of such technologies as Big Data, Cloud Computing, Internet of Things

Figure 1. A conceptual graph of the circle and the phenomenon

and a plethora of social engineering tools. These technologies enable integration of massive, scattered datasets, efficient interpretation of the integrated data, and speedier communication of the information. An obvious benefit is that with a huge amount of information being made available, the cyber-world becomes more transparent and netizens are better informed. And the bad is that there emerges a plethora of additional security threats bred in the loopholes in the new technologies, in the use of them or in the facilities enabled by the massive volume of data they generate, which the cyber-miscreants are ever lurking around to exploit when detected. However, that numerous clandestine activities are brought to light, for example, the Snowden episode (*South China Morning Post*, 2013) and the Panama Papers leak (Wilson, 2016), can be beneficial to some people/organizations and adversary to others.

Data Privacy Protection Problem

The problem is rooted in the way the data are collected about and are used adversely against

data subjects, and the *right* of the data subjects to that data, and has to deal the *techno-ethical-risk* which is originated in the way the technology is applied and the human users of the technology and the data, though the technology per se is neutral, yet the use of the technology is not (Parker, 1986; Neumann, 1995; and Williams, 1997). The protection of data privacy means to ensure that data privacy is not breached, that is, the data content is securely stored and accessed only with proper authority, and that the right of the data subjects not abused. Solving the problem means developing, reviewing, and implementing information protection and data privacy policies, standards, guidelines and processes (the policies), and mitigation measures; and to identify new technology risks; and to ensure that the policies are appropriately enhanced, communicated and complied with, and that mitigation measures are properly implemented.

The issue of data privacy invasion and the harmful impacts thereof have extended beyond the individuals and corporations to the regional/national governments, instanced by the UK House

of Commons' advocating a data ethics council and more urgency on data privacy, and sometime later the UK Government accepting the data ethics council proposal (*Computer Weekly*, 2016). These are strong reasons to suggest that data privacy security is no longer a personal and corporate concern but also a concern of governments, and international organizations, much more so than ever before.

Data Privacy and Concept of Data Privacy Category

Data privacy, which is basically about collecting and using the data about individuals and organizations, and the right of the data subjects to that data, is hitherto taken as a personal (individual) issue; it can be impersonal (corporate) as well. It is *personal data privacy* if the data subjects refer to individuals; it is *corporate data privacy* if the data subjects refer to organizations including government agencies. For example, the secret formula that a corporation adopts in determining the special fringe benefits in addition the total annual remuneration (which is normally published in the annual report) as a means to retain the service of their top-ranked staff is not trade secret but corporate privacy, and accessing or revealing without authority is an act of breaching corporate data privacy.

This the categorization is necessary. There are two supporting reasons for this view. The first reason is that an individual making a decision differently depends on his/her role: "as a member of an organization, the individual makes decisions not in relationship to personal needs and results, but in an impersonal sense as part of the organizational intent" (Barnard, 1938). The second reason is that the consequences of data privacy breach might mean differently to the individual vis-à-vis a group (organization) due to four considerations. The first consideration is the data owner's right to control over the access to and use of the information. The second consideration is the owner's integrity and provision of confidential data that include such

personal data as biometric measurement (in the case of individuals) or corporate data as the formula adopted by a company to determine the hidden portion of benefits in each senior executive's total annual remuneration (hidden because such information is usually withheld from a company's annual report) (in the case of business concerns) (bodily privacy). The third consideration is the data being observed by surveillance and the like (behavioural privacy). The last consideration is freedom of communication that includes speech or expression and dialogue with third parties (communicational privacy).

The dichotomy is recognized in the International Data Privacy Principles (Zankl, 2016), but generally missed in the extant data privacy laws which are inherently inadequate or unable to judge corporate data privacy infringement. It pays, it is argued, all stakeholders, particularly those involved in law making and enforcement, and the information security scholars and practitioners to be clear about the hitherto muddled concept.

Data Privacy Protection and Changes in Demand and Status

Data protection has long been regarded as a technical and economic matter and requires technical actions to ensure accuracy, completeness, integrity and availability of the data content, and to admit only authorized access. However, the impact of scope and level of data privacy breach has changed, extending from personal/corporate to governmental and the UK government pronouncement alluded earlier proves a case in point). Also, the nature data privacy breach has changed because the problem and the consequences thereof are found to be of techno-economic as well as legal, ethical, social and ecological.

Limitations of the Extant Policies and Code of Conduct/Practice

The policies and standards in current use are invariably *dated* due to the rapid advances of the

technologies, *limited* to cope with techno-socio threats, a product of the technology-driven information phenomenon, and *inadequate* to deal with the well-equipped and cunning cyber-miscreants. This is an obvious shortcoming.

Further, the policy statements tend to be vague and less than user-friendly or simply difficult to absorb and follow, easily forgotten and probably ignored in the end. For example, a 70-page Code of Professional Conduct for the Registered Medical Practitioners (Hong Kong Medical Council, 2009) is certainly unpalatable for the busy doctors. Another case in point is that when asked, the Deputy Commissioner of a police force could not tell what the code was, though he admitted being aware of one in existence and posted on the force's web-site. Alluded to earlier, the text of the policy and the code tend to be difficult to comprehend, wordy and lengthy. This is another limitation.

On the one hand, the extant policies usually focus on the quantitative/tangible/technical efficiency (aiming at achieving targets against such indicators as *return on investment* (ROI), *net present value* (NPV) and *payback period* based on cost-benefit (Portney, 2008) and risk (Wharton, 1992; Moore, et al, 1976) considerations), and satisfying the minimum requirements of the law), and in some cases, ethical acceptability embedded in professionalism but hardly touch or miss the qualitative/intangible social desirability (despite the rhetoric by some organizations in response to *corporate social responsibility* CSR) and ecological sustainability (despite Green Computing which advocates environment-friendly and paper-free design and application). On the other hand, professionals (in the field of Science and Technology, like others) are nurtured under the influence of the *misinterpretation of risk* and the *flawed curricula* across science and technology (Lee, 2015b), and their decision-making mentality developed along the Simon doctrine which is essentially to “select the alternative, among those available, which will lead to the most complete achievement of your goals” (Simon, 1976b).

The goals are not necessarily personal despite the personal possessive adjective, according to Barnard (1938) who asserted that “the decisions that an individual makes are quite distinct from his personal choice” so as a member of an organization, the individual makes decisions not in relationship to personal needs and results, but in an impersonal sense as part of the organizational intent. This is why the policy, a product of our decision, and also the code of practice/conduct is inherently technical and financial, and evaluated in terms of financial performance/economic value, and found short when dealing with many a problem commonly found in *post-implementation* and *post-contract* situations, for example, that IT professionals face daily are of an ethical and/or a social nature. This is an inherent weakness, the hidden reason.

Given a code of conduct, an organization lacks effective measure to encourage staff to familiarize with and to act according to the code. It is not uncommon to find that the code exists in name and not in substance. This is arguably a limitation, definitely an operational issue.

RECOMMENDED SOLUTION

Information security policy is propelled to centre-stage by the protection problem, and the front-line functional group is among the first to bear the brunt. To alleviate some burdens on the front-line information security staff who are always working against a tight schedule, a handy reference or a quick guide in the form of a code of conduct or practice, into which the gist of the adopted policies is incorporated, as an aid, was conceived. This document will contribute to cultivate a corporate culture of ethics conducive to the compliance with the data privacy protection policy organization-wide. A framework that comprises a 6-d code based on the 6-d metric and an operationalization scheme to make the code work, is proposed.

The Hexa-Dimension Metric and its Rationale

The hexa-dimension LESTEF (pronounced “*lest ye forget*”), which was initially conceived as a checklist for decision making in technology-driven and information-intensive organizations, is proposed for developing a code of practice or corporate charter as an aid for ensuring and enhancing information security policies including data privacy preservation. By implication, hefty amount of money is invested in the expensive technologies, thus it is a matter of course to expect a justifiable return on that the investment (*financial viability*) and an optimized utilization of the technologies (*technical effectiveness*). In the same vein, huge amount of information that is generated can be abused, thus *legal validity*, *ethical acceptance*, and *social acceptability*. Running the technologies consumes a lot of natural resources (electricity, water, paper, etc.), and generates air, noise pollution, thus *ecological sustainability* – the six attributes representing efficiency (requirements) of the hexa-dimension model.

The Hexa-Dimension Code of Practice/Conduct

Code of Conduct

In general, a code of conduct or practice comprises a set of rules and regulations that encapsulate the gist of the policies and standards adopted by the organization. It has arguably the capability to provide a guide, a handy reference, and a reminder to the stakeholders, especially the constantly busy front-line operational staff.

If properly and appropriately formulated and articulated, the code would be useful in permeating the policies and standards throughout the organization and around, thus cultivating a corporate-wide ethical, professional conduct. While such codes may serve to deter potential offensive actions, they are limited in driving home those rules or standards as they can rely only and purely on the

moral obligation of the stakeholders concerned primarily because violation of the code by itself does not in general attract any criminal charges. Auxiliary measures must put in force to arrive at desirable results, such as executive actions that empower to grant rewards and to impose punishment (for example, annual performance appraisal).

The Hexa-Dimension Code

Organizations of various varieties might have some kind of code of practice in place. However, the extant codes invariably tend to focus on technical, financial and probably legal issues; they are insufficient when considering also social, ethical and probably ecological issues. The hexa-dimension code based on the hexa-dimension model poises to make up for the deficiency.

Operationalization Schedule

Prerequisite

To operationalize requires the support of the Board of Directors with respect to corporate policy aspects and the supporting infrastructures that include the organization’s human resources management (HRM), legal, finance, and ICT functional units with respect to technical support and reference, and mandatorily, and an appraisal of ethical consistency in conduct be included in an annual performance review (by the HRM Department). In addition, and ideally, GCF Computing (Patrignani & Whitehouse, 2014) be adopted. The characteristic features of GCF Computing are provided in Table 1.

Procedure

There are three major preparatory steps (summarized in Table 2):

- Identify the relevant critical factors depending on the target end-users (corporate-wide or a functional unit, nature of opera-

Table 1. GCF computing

GCF	Target	Enabler	Contribute to
Good Computing	Workable & technically efficient deliverables	Internet technologies, Big Data, Cloud Computing, Ubiquitous computing (Evasive Computing), etc.	Legal, Technical & Financial efficiencies
Clean Computing	Energy & materials saving	Green Computing	Environmental efficiency
Fair Computing	Corporate social responsibility	Ethical Computing (Lee, 2015b)	Social & Ethical efficiencies

Table 2. Schedule of operationalization

Generic				User specific	
Attributes/ Factors	Remarks	Control	Targets	Drivers (*)	Supported by
Legal validity	Abiding the law, rule & regulations currently in force	External	Local law and convention	Corporate counsel /legal dept.	Good Computing
Social desirability	Beneficial to all stakeholders including the general public	External	Local culture and habit; standards for perceivable benefits to primary stakeholders and the public		Fair Computing
Ecological sustainability	Friendly to natural and industrial/business environment	External	Policy/guidelines for energy/ materials saving; ecology related law (if any)		Clean Computing
Ethical acceptability	Consistent with ethical principles	Internal	Corporate social responsibility; corporate culture	PR, HRM	Fair Computing
Technical effectiveness	Use up-to-date technology to meet targets effectively and efficiently	Internal	Sufficient & necessary human & technological resources to support infrastructural support	ICT, HRM	Good Computing
Financial viability	financially sound and viable	Internal	Corporate policy (performance metrics: operational goal, risk absorption standards & limits, etc.)	Finance, Operations	Good Computing

tion – for example, environmental impact is critical for a mining company or a factory, but may probably be skipped for an Information Security Unit)

- Secure the support of the Board of Directors and the supporting infrastructures including in an annual performance review to assess awareness and compliance of the code in carrying out assignments/duties (by the HRM Department).
- Determine a schedule for quantifying the elements of each factor for measuring, prioritizing and balancing the factors. Depending on the attributes/factors deter-

mined, the steps to be taken to measure the effectiveness.

Briefly,

- Legal validity is to ensure that the laws current in force and the organization's rules and conventions are abided at the advice of the corporate counsel or the Legal Department, and is measured by the extent and degree the law is obeyed.
- Social desirability is to make sure that the benefit of all stakeholders including that the public has been considered and deliberated

consistent with local culture and habit and can be measured by survey results of the extent of public benefited based on the ethical principles of utility and consequence.

- Ecological sustainability means the actions taken must be friendly (not harmful) to the environment and is measured by indication of energy/materials saving, noise and air pollution, radiation emission rate and so on using EIA (environmental impact assessment) (Hong Kong Government).
- Ethical acceptability demands that the actions taken must be consistent with ethical principles with the help of the corporation's Public Relations Unit and Human Resource Management Department, and can be measured using the Ethical Matrix method (Lee, 2015b) to assess the consistency with the relevant ethical principles of duty and reciprocity.
- Technical effectiveness means using up-to-date technology to meet targets effectively and efficiently.
- Financial viability is to ensure that the actions taken are financially sound and viable consistent with the corporation's performance metric on operational goal, risk absorption standards and limits, etc. as advised by the Finance and Operations experts, and is measured by ROI and NPV.

FUTURE RESEARCH DIRECTIONS

The concept that a decision should meet the six criteria is new, but each criterion in the hexa-dimension metric model is not new. The metric has the potential to serve others purposes, for example, Management Science, in enhancing identification and evaluation of the relevant factors of the traditional and popularly adopted decision model like the rationality and logic based Simon model (1976) which is no longer sufficient because decision makers are not always rational and sometimes non-rational, or judgmental decision making based procedural or bounded rationality

(Gigerenzer, 2001) and escalation of commitment decision making that “under certain conditions, decision makers who make an initial decision become overly committed to the original choice and then subsequently make decisions biased by psychological commitment” (McCarthy, Schoorman and Cooper (1993, p. 9). Also, that the decision variables are formulated and measured mainly in economic terms must be updated as they are also legal, ethical, social, and more recently, ecological in nature. This raises many questions that seek an answer, to name a few:

- The hexa-dimension code can be a prototype for designing a code of practice for an IT organization, as proposed in this article. At this exploratory stage, is efficiency needs to be demonstrated, field-tested and validated against actual results. An on-site study of its effectiveness as a handy reference at the different levels of the corporate is also a worthwhile exercise.
- The code, which aims to be a handy reference for the stakeholders, particularly employees, would not by itself brings about the results desired; supporting infrastructures including human resources management action such annual performance appraisal and so on, must be in place and work in concert. This raises two research questions: How the mechanisms concerned are coordinated and cooperated, and can corporations or functional units expect an effective enforcement of the code of practice and an ethical atmosphere be cultivated corporate-wide or within a functional unit after a compulsory annual appraisal scheme that includes an assessment of ethical/social elements in the assigned duty is in force.
- An empirical study of applicability and acceptability of the hexa-dimension metric to enhance the chance and scope of finding factors likely to bring about ethical, social and ecological repercussion on decision making warrants serious consideration.

CONCLUSION

The information security professionals are in urgent need of effective and pragmatic guidance as the information security function in a technology-driven information-intensive environment becomes more complicated and harder due to the new socio-techno risks and data privacy protection becomes a primary concern as privacy infringement occurs more frequently and leads to potentially devastating consequences to the individuals, corporations and governments. The newly developed framework, though at this embryonic stage of growth still awaiting empirical evidence and popular acceptance in the IT arena, poises to play a useful role, in addition to the Personal Data (Privacy) Ordinance (Hong Kong's privacy law) (Chang, 2016), the International Data Privacy Principles (Zankl, 2016), to release the burden on as the extant policies and standards. It noteworthy that

- An international standard is useful and necessary when regular (hard) law often fails to handle issues such as those arising from inter-border data transfer or cross-border trading and when formulating corporate policies that meet not only legal but also ethical demands.
- Privacy laws of many jurisdictions are based on the principle-based OECD Privacy Guidelines. Many of these principles have been implemented by jurisdictions across the globe including Australia, Canada, Hong Kong and the UK, and the ethical dimensions of these principles have been realized and expressed in legal terms. Organizations have found themselves insufficient to follow just the letters of the law, but also the spirit, as the public understand and expect their privacy rights.
- The hexa-dimension Code of Conduct/ Practice aims at alerting stakeholders to

exercise their duties such they are not breaking the law in force; not harmful to the individuals and society at large; not wasteful of the resources available (the computer facilities, the workforce, the budget, etc.); and are environmentally-friendly. Since different organizations have their own unique policies, thus code of conduct, there can be no universal receipt but a general guideline. Since the code by itself is limited in enforcing compliance with the policies and standards, a framework was developed and a 3-step procedure are recommended.

- Decision makers may face unavoidable competing circumstances when considering the issues of ethical and social nature, and balancing the competing issues is necessary in resolving them. Apart from the linear menus, the Ethical Matrix (Lee, 2015b) is worthy of consideration.
- The hexa-dimension code of practice will be of interest not only to the information security personnel but also to the practitioners and scholars in Information Science and Technology and perhaps other fields such as Information Systems Audit, Management, and Public Policy.

KEY TERMS AND DEFINITIONS

Data Privacy: Can be personal data privacy if the data subjects refer to individuals or corporate data privacy if the data subjects refer to organizations including government agencies.

GCF Computing: Slow Tech is not a technology that is slow but a movement that parallels with the same concept of the Slow Food movement. Slow Food International claimed in 1989 that the Slow Food Movement was set up to “counter the rises of fast food and fast life”: to strive for good food (food that tastes good, is a pleasure to eat and selected according to its quality), clean food (food that is produced by such a process that respects the environment and should promote biodiversity and sustainability), and fair food (food that is cultivated and produced by ways that must respect the farmers). GCF Computing (Good Computing, Clean Computing, Fair Computing) was proposed and defined following the Slow Tech concept (Patrignani & Whitehouse, 2014).

International Data Privacy Principles: Comprise 13 principles (Zankl, 2016).

Operationalization Scheme: Acquire Board's endorsement and infrastructural support from other relevant departments, and determine the relevant criteria/factors according to the nature of the problem and the target users and a quantification system for measuring against and balancing the criteria.

PDPO Data Protection Principles (DPP): (1) Data Collection and Purpose; (2) Accuracy and Retention; (3) Data Use; (4) Data Security; (5) Openness; and (6) Data Access and Correction (https://www.pcpd.org.hk/english/data_privacy-law/ordinance_at_a_Glance/ordinance.html).

PDPO: Personal Data (Privacy) Ordinance (Hong Kong's privacy law), enacted in 1995 (<https://www.pcpd.org.hk/english/files/pdpo.pdf>).

Post-Contract Problem (an example): The specification was approved by provider and client, and contract duly signed. A senior project consultant who was assigned to the project discovered a fault in the specification, a fault in the inventory control function. Inventory control is a critical function for the business of the client, a fashion boutique, because supply and demand of the goods for sale is time-critical and zero error-tolerance is

expected according to the specification. The fault was confirmed after the consultant's site visit. The consultant faces the dilemma: Keep quiet or tell the boss or the client or both.

Post-Implementation Problem (An Example): An online monitoring system was implemented to replace an existing offline help-desk platform. The Executive Vice President (EVP) is impressed by the performance, particularly the online monitoring capability provided by the system, and asks the Chief Information Officer (CIO) to have a copy of the system installed in her office to track drug dealing allegedly taken place on company premises. Dilemmas that need to be addressed include deviation of approval of acquisition, privacy invasion, corporate image damage, professionalism (CIO), duty (EVP); treated as a means (staff); staff morale & corporate policy (Firm).

Technology-Driven Information-Intensive Phenomenon: A state that characterizes the modus operandi in cyberspace and attributes to the vicious circle: More and more information is needed to sustain more transparent business operations, thus satisfying the more demanding consumers of information; higher utilization of more technologies is needed to generate more information to handle the enlarged data volume, and to further increase the processing speed.

The Data Privacy Protection Problem: To develop and implement data privacy policies, standards, guidelines and processes (the policies), to ensure that the policies are appropriately enhanced, communicated and complied with, and to devise a set of effective mitigation measures.

The Solution: A *hexa-dimension code of practice*, a list of rules and regulations that encapsulates the gist of the policies and standards adopted by the organization, and embraces the six criteria.

Information and Communication Technology Ethics and Social Responsibility

Tomas Cahlik

Charles University Prague, Czech Republic & University of Economics Prague, Czech Republic

INTRODUCTION

Information and Communication Technologies (ICTs) have penetrated during the last 20 years all human activities everywhere on the Earth. Humanity has entered into the information age, virtual reality and even virtual worlds have been created.

The basic ethical questions stay as they have always been: How are we to live? What are we to be? Basic answers are, of course, that we ought to live good lives and be good persons.

The aim of this article is:

- To specify what “living a good life” and “being a good person” could be in the information age;
- To identify some challenges and opportunities ICTs offer in this context.

Having absolutely stabilized basic questions and basic answers makes the methodology of ethics quite different from the methodology in sciences. In sciences, one starts with a thorough review of previous research, specifies some new and interesting research question, makes hypotheses about possible answers and bases argumentation on data. In ethics, one reflects problems of the current age in a mirror that was created centuries ago and has been polished by many ethical reflections ever since. Forms of ethical texts are rich: dialogs, even poems, but the most used form is an essay.

BACKGROUND

Literature review in research articles is used for showing that the research described in the article fits into research themes that are interesting for contemporary research community. Literature review in ethical reflections is used differently, just for illustration of ideas that have been published in the area of interest and for “opening the scene”.

Looking into the Web of Science database in September 2015 and using keywords “information technology”, “ethics” and “social responsibility” 60 entries are obtained (from that 55 articles or conference proceedings), 31 entries being published since 2010. This reveals not high but steady and increasing activity on the interdisciplinary border between ICTs and that part of ethics that is linked to social responsibility.

Looking closer into the content of those articles, following themes can be identified in the last decade:

- Ethical questions linked with the creation and use of “big data”, including creation of agreed standards of good practice - e.g. (Rizk&Choueiri, 2006), (Light,& McGrath, 2010), (Celen, & Seferoglu, 2013);
- Development of sustainable information society - e.g. (Tsai&Chen, 2013), (Busch, 2011), (Niemela&Ikonen&Leikas&Kantola&Kulju&Tammela&Ylikauppi, 2014)

in the sense of an inclusive and environmentally friendly society; application of precautionary principle in the development of ICTs (Som&Hilty& Kohler, 2009);

- Corporate social responsibility of both ICT suppliers and users – e.g. (Tsai&Chen, 2013), (Busch, 2011), (Vaccaro&Madsen, 2009), including suggestions for standards of good practice (Patrignani&Whitehouse, 2014) and how to enable consumers to push companies to behave ethically with the use of ICTs (Watts& Wyner, 2011);
- University social responsibility (Arntzen, 2010); new teaching and learning culture based on ICTs (Stepien, 2010).

This indicates research activity that is driven by applications and can be contrasted with the research activity from the years before, that was pushed by theoretical considerations. (Lianos, 2000) e.g. starts with sociological concepts and identifies the threat that ICTs can atomize society through making development of personal trust obsolete. Lianos uses credit card as an example: one does not need to be trusted by the provider of money, the only thing that is relevant is the validity of the card. Technical norms replace moral and social norms.

Research fields may have different dynamics. It is quite usual that after the theoretical development some themes or even the whole field dissolve in applications. Nevertheless, after some time, both practitioners and applied researchers may find it useful to return to more generalizing theoretical reflection. In this article, the most general level of ethical reflection is being considered.

Ethics as practical philosophy offers a lot of valuable ideas that have been generalized from the real life problems of the whole human history. In this article, especially ideas developed by utilitarian philosophers, existential philosophers and the proponents of the “virtue ethics” can be identified. Two more areas of ethics linked with this article are “ethics of norms” and “casuistry”. Readers are advised to find more detailed summaries of those three schools and two areas on web.

“LIVING GOOD LIFE” AND “BEING A GOOD PERSON” IN THE INFORMATION AGE

Issues, Controversies, Problems

Let us identify three challenges and three opportunities ICTs directly offer in the context of ethics. This gives a framework to this article from which the discussion of economic costs and benefits stays mostly out, even if economic costs and benefits surely have ethical impacts.

Specification of the first challenge builds upon the above described conclusion in (Lianos, 2000) that technical norms replace moral and social norms. Problem is that the network of moral and social norms has always been considered as something absolutely necessary for the identity of specific society and that the dissolution of this network means atomization and threatens the whole society.

The second challenge is linked with the current research frontier of ICTs, with virtual reality. Economic and social thinking is strongly based on utilitarianism and its basic persuasion that for having a good life pleasures must be maximized and pains minimized. ICTs allow creating a virtual reality in which the choice of pleasures is almost unlimited and in which we are able to avoid pain. The basic question here is the authenticity of such a life. It can be easy and pleasant but it loses any sense.

Above the basic utilitarian life level, another level ought to be built in which we ask if our activities are right. What is the right activity has been discussed in Western thinking for centuries since Plato and two basic outcomes are as follows:

- In a right activity, humans are used not as tools only. E.g. authors of new software ought to take into consideration not only how much they earn but if the software allows better self-realization of users, too;
- Real circumstances must be taken into consideration in following the basic target of

“being better humans”. E.g. software firms must follow the profit motive as well as the moral one to stay in the business.

ICTs have not changed these basic outcomes but have surely changed the real circumstances and this opens the stage for discussion of what the right activities are in these changed circumstances. All new technologies have always done this, but what makes ICTs specific is the scale and speed of change.

One lives a good life if one realizes his or her potential in right activities. A person can develop its potential and become a virtuous person through cultivating its virtues and fighting its vices. Good people are virtuous people and there exists a positive correlation between being good people and doing right activities. So there exists a strong link between being a good person and living a good life.

The second challenge of ICTs lies in the possibility that people could be sucked too much into the virtual reality, enjoy pleasures there and try to avoid reality. Their lives would lose authenticity and they would not leave the basic utilitarian life level. Impacts on both the individual and society would be analogic to impacts of drugs addiction.

There exists a positive feedback between the first and second challenge: instead of being identified with a real society existing at some geographical place, people are identified with the usually anonymous social group sharing the same virtual reality. In the process of atomization of real society, the motivation for its members to find substitutes of social ties in virtual reality increases. This closes the loop.

In this context, we could ask about the geo-political impact of having socially atomized countries in which a lot of citizens avoid reality together with socially homogenous countries where people live more in reality. Let us imagine a possibly violent conflict and ask who would probably win in such a conflict? Or let us imagine mass immigration of people from the second type of countries to a country of the first type. What would happen? It is surely not socially responsible to ignore these scenarios.

The first opportunity of the virtual reality ICTs have created lies in quick detection of suspect economic, political and other social activities in a real society and in facilitating the discourse about such activities. By definition, discourse is discussion in which participants are free in the sense that they are not influenced by exogenous incentives or constraints in the expression of their opinions. Virtual reality, if it is free - without censorship - and anonymous offers an optimal environment for discourses on any topic. Discourses on suspect social activities help to create socially accepted moral norms and push firms and politicians to social responsibility.

The second opportunity lies in the enormous educational potential of the virtual world. For Aristotle, being educated was considered to be a virtue by itself, even if not being a moral virtue. For Plato, if people just knew what were right they would behave in that way. It may be too optimistic but we know that there exists a negative correlation between educational level in a country and e.g. crime.

Instead of discussing this intuitively clear opportunity on general level let us illustrate how ICTs can be used for benchmarking and looking for best practices in ethical issues. In (Codes of Ethics Collection), there are thousands of different ethical codes. Each of them presents norms that have been accepted by some organization (firm, association, university etc.). Ethical Codes are classified according to professional categories, one of them being “Computer and Information Science”. In September 2015, 56 organizations are found in this category, some of them with ethical codes for specific activities, some of them with different versions of the same code showing how it has been developed in time.

Any organization interested in development of its ethical norms can use this enormous source to compare the norms it already has with norms of its peers in the Codes of Ethics Collection. In an internal discourse, it can then formulate and accept the best for itself.

We can see another positive feedback, now between both opportunities: educational material easily accessible through ICTs can be used in discourses and additional knowledge created in discourses becomes easily accessible through ICTs.

The third opportunity lies in using ICTs for supporting the creation of virtues and the third challenge in supporting the creation of vices. The lists of moral virtues and vices have been changing during the centuries since Aristotle and there is not full consent about what ought to be on the lists. The most of virtues and vices get stronger with the repetition of either good or bad activities.

Let us take the (List of virtues) and (List of vices) from the webpage <http://www.virtuescience.com/>, choose some of them and analyze how they can be strengthened by ICTs. (We could surely take any other list, but the advantage of these two lists is that the list of virtues has 120 items and the list of vices 17 only. This supports the optimistic attitude towards human nature.)

“Compassion” and “Charity”: ICTs allow watching repeatedly and with high frequency poor people around the World what develops compassion among the most of watchers; psychologically especially among young people who are in the same time the most knowledgeable users of ICTs. This positive correlation can make this effect quite strong. ICTs offer a very easy way (e.g. donation through SMS) to do charitable activities what makes compassionate people to do such activities repeatedly. This strengthens the virtue charity.

“Curiosity”, “Commitment” and “Creativity”: Anderson in (Anderson, 2010) describes a nice example how web video powers global innovation. A slum boy watches video with street dance. Watching wakes up his curiosity and he makes commitment to master street dance himself. He surely has to be highly creative in transferring the knowledge from video into reality. There are millions of different activities and millions of web users, many of them behaving similarly as the slum boy, so ICTs have a very strong effect on these three virtues.

“Enthusiasm” and “Cooperation”: For economists, it is really difficult to explain the very existence of the open source software or Wikipedia because of non-existence of material incentives. Possible explanation is following: Knowledgeable users of ICTs are usually quite enthusiastic about the possibilities ICTs offer. They form a global community and identify strongly with this community. This has created the situation in which they like to cooperate not for material benefit but for achieving a shared goal. This works if individual costs of cooperation are negligible, what they with the use of ICTs can really be. Social benefits are enormous.

“Chastity” as a virtue or “Lack of Chastity” as a vice: In this context, pornographic content of web sites ought to be discussed. Watching pornography repeatedly creates habit - sometimes addiction – and weakens chastity. This discussion is not relevant for all World societies, e.g. in Japan people do not consider chastity as having sexual context. Watching pornography is clearly linked with the second challenge of ICTs discussed above; real sexual activity can shift to virtual reality what could have demographic impacts.

“Sloth”: Let us understand laziness as aversion to be active in the real world. Being active in that part of virtual reality that overlaps with reality perhaps weakens sloth; ICTs can increase the efficiency of our real activity what increases our motivation for doing it. Problem is that ICTs have created an enormous potential for procrastination – for doing less urgent but pleasurable tasks in preference to more urgent but less pleasurable ones. The seductive power can be strong and yielding to temptation is surely positively correlated with sloth.

Solutions and Recommendations

The positive impact of above discussed opportunities can neutralize or outweigh the negative impact of above discussed challenges - threats. We cannot say for sure what happens because we know that all systems with positive feedbacks can considerably and dis-continually change very

quickly their behavior and that it is impossible to predict when the change comes and what the behavior of the system would be after the change. Similar situation has occurred with the spread of each new technology and some recommendations can be done based on historical experiences.

It would not have any sense to try to stop the development of ICTs, it is simply impossible. What is possible is to try to increase the costs of ICTs activities that are negative from the ethical point of view and to increase benefits of activities that are positive from the ethical point of view. If it ought to be done, how to do it and who ought to do it opens a lot of questions. Let us take as an example the possibility of censorship.

Censorship can decrease negative impact through forbidding access to pages that could create addiction. Problem is that it constrains freedom in the virtual reality that is the basic condition for using up the opportunities of ICTs. In each society, some equilibrium level of censorship has been created that reflexes different opinions on this issue. Both opinions and the equilibrium shift in time, we can imagine that in Western societies more www pages than child pornography could be blocked and in China some of the currently blocked www pages could be unblocked.

Previous example shows that discourse of ethical issues linked with ICTs can never stop and that all members of society have responsibility to take part in it.

FUTURE RESEARCH DIRECTIONS

Following research questions would deserve more attention:

- What is the impact of ICTs on social identity? Could possible changes in social identity have a geo-political impact?
- What other virtues and vices are influenced by ICTs and how?

- Is it possible to increase the costs of ICTs activities that are negative from the ethical point of view, ought it to be done and by whom?
- Is it possible to increase the benefits of ICTs activities that are positive from the ethical point of view, ought it to be done and by whom?

CONCLUSION

ICTs offer a lot of possibilities and present some challenges – threats - for living a good life in the ethical sense and being a good person. It is impossible to predict if the positive impacts outweigh the negative ones. Anyway, it is impossible to stop the development of ICTs. The question is if the society ought to try to increase the costs of ICTs activities that are negative from the ethical point of view and to increase benefits of activities that are positive from the ethical point of view, who ought to do it and how. All members of society have responsibility to participate in discourse of this question.

KEY TERMS AND DEFINITIONS

Casuistry: Branch of ethics that uses case studies to make clear moral principles and norms in typical situations. All ethical codes specify some norms of conduct. These norms are usually explained with the use of different case studies.

Existential Philosophy: Branch of Philosophy that starts with individual existence and the problem of its being in the World. Important predecessor was Søren Kierkegaard (19th century), among

main representatives we can find Martin Heidegger and Jean-Paul Sartre (both 20th century). They looked for authentic existence and have found different solutions depending especially on the religiosity of the specific philosopher.

Ethics: Practical philosophy, scientific analysis of moral contents.

Ethics of Norms: Branch of ethics that analyses the structure of norms and what they are based on.

Norms: Norms are the shared and sanctioned rules. Sanctions can be both formal (e.g. law) and informal (e.g. pressure of social group).

Utilitarianism: Branch of ethics that bases moral reasoning on consequences of actions. Actions are good if they maximize pleasure and

minimize pain. Among grounders are Jeremy Bentham and John Stuart Mill (18th -19th century). It has penetrated the mainstream economics. It can be shown that total utility of consumers can be increased by redistribution.

Virtue Ethics: Branch of Ethics that considers humans as being bearers of given or developed virtues. Humans have to develop virtues and fight with vices for becoming good. Basic concepts go back as far as to Plato and Aristotle (5th, 4th century BCE).

Virtual Reality: Created and accessed by ICTs. It usually overlaps with “reality” but the overlapping is changing and fuzzy. Extremes of Virtual Reality are Virtual Worlds, in which “avatars” of humans can live parallel lives.

Intrusion Tolerance Techniques

Wenbing Zhao

Cleveland State University, USA

INTRODUCTION

Intrusion tolerance refers to the capability of maintaining the system availability and integrity despite malicious attacks. Intrusion tolerance has been a hot research area for more than a decade and various techniques have been introduced to achieve various degrees of intrusion tolerance (Castro & Liskov, 2002; Chai & Zhao, 2014 June; Chai & Zhao, 2014 August; Deswarte et al., 1991; Verissimo et al., 2003; Yin et al., 2003; Zhao, 2013; Zhao, 2014). Such techniques can tolerate intrusion attacks in two respects: (1) a system continues providing correct services (may be with reduced performance) and (2) no confidential information is revealed to an adversary. The former can be achieved by using the replication techniques, as long as the adversary can only compromise a small number of replicas. The later is often built on top of secret sharing and threshold cryptography techniques. Plain replication is often perceived to reduce the confidentiality of a system, because there are more identical copies available for penetration. However, if replication is integrated properly with secret sharing and threshold cryptography, both availability and confidentiality can be enhanced.

BACKGROUND

In this section, we introduce some basic security and dependability concepts and techniques related to intrusion tolerance. A secure information system is one that exhibits the following properties (Pfleeger & Pfleeger, 2002):

- **Confidentiality:** Only authorized users have access to the information.
- **Integrity:** The information can be modified only by authenticated users in authorized ways. Any unauthorized modification can be detected.
- **Availability:** The information is available whenever a legitimate user wants to access it.

Confidentiality is often achieved by using encryption, authentication, and access control. Encryption is a reversible process that scrambles a piece of plaintext into something uninterpretable. Encryption is often parameterized with a security key. To decrypt, the same or a different security key is needed. Authentication is the procedure to verify the identity of a user that wants to access confidential data. Access control is used to restrict what an authenticated user can access.

Integrity can be protected by using secure hash functions, message authentication code (MAC) and digital signatures. For data stored locally, including the application binary files, a checksum is often used as a way to verify data integrity. The checksum can be generated by applying an oneway secure hash transformation on the data. Before the data is accessed, one can verify its integrity by recomputing the checksum and comparing it with the original one. The integrity of a message transmitted over the network can be guarded by a MAC. A MAC is generated by hashing on both the original message and a shared secret key (and often with a sequence number as well). If it is tampered with, the message can be detected in a way similar to that for checksum. For stronger

protection, a message can be signed by the sender. A digital signature is produced by first hashing the message using a secure hash function, and then encrypting the hash using the sender's private key.

High availability is achieved by using replication, checkpointing and recovery techniques. Replication is a technique that relying on running redundant copies of an application so that if one copy fails, the services can be provided by the remaining copies. Checkpointing means to take a snapshot of the state of a replica. The saved state can be used to bring a new or a restarted replica up to date. Checkpointing is also useful to avoid log buildup (when a checkpoint is taken, all previously logs can be garbage collected). Recovery techniques concern the tasks of removing faulty replicas, repairing them, and reintegrating them back to the system.

INTRUSION TOLERANCE TECHNIQUES

Intrusion tolerance is built on top of two fundamental techniques: replication and secret sharing/threshold cryptography (Deswarte et al., 1991). In the context of intrusion tolerance, a very general fault model must be used because a compromised replica might exhibit arbitrary faulty behaviors. Such a fault model is often termed as Byzantine fault (Lamport et al., 1982).

Byzantine Fault Tolerance

An intrusion attack might bring a service down, or compromise the integrity of a service. An effective defense is to introduce redundancy into the system, i.e., to replicate critical components in the system. Assuming that an intrusion attack can only penetrate a small fraction of the replicas, the service availability and integrity can be preserved by the remaining correct replicas. However, achieving this goal is not trivial – we must ensure consistent execution of all correct replicas despite the attacks launched by faulty replicas.

A Byzantine faulty replica may use all kinds of strategies to prevent the normal operations of a replica. In particular, it might propagate conflicting information to other replicas or components that it interacts with. To tolerate f Byzantine faulty replicas in an asynchronous environment, we need to have at least $3f+1$ number of replicas (Castro & Liskov, 2002). An asynchronous environment is one that has no bound on processing times, communication delays, and clock skews. Internet applications are often modeled as asynchronous systems. Usually, one replica is designated as the primary and the rest are backups.

There are two different approaches to Byzantine fault tolerance. In a Byzantine quorum system (Malkhi & Reiter, 1997), read and write operations issued by some clients are applied on a set of data items (which consists of the state of a service). It is assumed that the read and write operations are synchronized. A read operation retrieves information from a quorum of correct replicas and a write operation applies the update to a quorum of correct replicas. In a system with $3f+1$ replicas, a quorum can be formed by $2f+1$ replicas so that any two quorums overlap by at least $f+1$ replica, among which at least one is not faulty. This guarantees the correct operations of the quorum-based system.

A more general method is the state-machine based approach (Schneider, 1990). In the state-machine based approach, a replica is modeled as a state machine. The state change is triggered by remote invocations on the methods offered by the replica. This approach is applicable to a much wider range of applications. Consider a client server application where the server is replicated using the state-machine based approach (Castro & Liskov, 2002). The client first sends its request to the primary replica. The primary then broadcasts the request message to the backups and also determines the execution order of the message. To prevent a faulty primary from intentionally delaying a message, the client starts a timer after it sends out a request. It waits for $f+1$ identical replies from different replicas. Because at most f

Figure 1. An example scenario showing the importance of totally ordering incoming requests

replicas are faulty, at least one reply must come from a correct replica. If the timer expires before it receives a correct reply, the client broadcasts the request to all server replicas. This enables the correct replicas to detect the primary failure so that a new primary can be elected (this is often called a view change).

All correct replicas must agree on the same set of input messages with the same execution order. In other words, the request messages must be delivered to the replicas reliably in the same total order. To understand this better, consider the scenario illustrated in Figure 1. There are four server replicas R_1 , R_2 , R_3 , and R_4 , and two clients C_1 and C_2 . Client C_1 multicasts a request m_1 to all the replicas, and concurrently, the other client C_2 multicasts another request m_2 to all the replicas. Without controlling the ordering of the messages, it might happen that R_1 and R_2 deliver m_1 ahead of m_2 , and R_3 and R_4 deliver m_1 after m_2 . Assume that the initial state at each replica can be represented as an integer with a value of 10, the request m_1 asks for the addition of 5 to the state, and the request m_2 asks for the doubling of the state value. With the different ordering, state at R_1 and R_2 after processing m_1 and m_2 would be 30 while the state

at R_3 and R_4 after processing m_2 and m_1 would be 25. Hence, the states of the replicas diverge due to inconsistent request delivery ordering.

Furthermore, replicas may not process the same request deterministically, i.e., given the same request (delivered in the same order to all replicas), they may not produce identical reply. There are many factors that can cause non-deterministic execution of a request, e.g., differences in local clocks, process identifiers, and many other local resources that might be referenced by the replicas, and multithreading. These factors must be controlled properly so that the replicas appear to execute deterministically. This is a rather difficult task in the face of Byzantine fault. Until recently, the issue was addressed in a very limited manner, for example, by assuming that the replicas are single-threaded and all non-deterministic operations are known a priori. The primary replica determines the values to be used for all replicas and disseminates them to the backups. The backups subsequently verify the proposed values. If the primary is detected to be faulty, a view change is initiated. Recently, we introduced a framework that systematically handles various types of replica nondeterminism (Zhang et al., 2011).

Byzantine fault tolerance mechanisms tend to suffer from scalability problems. Amir et al. (2006) have tackled the size scalability problem by using a hierarchical replication architecture so that Byzantine fault tolerance can be achieved in large scale application running over wide area networks. Aiyer et al. (2005) considered the challenges faced by ensuring Byzantine fault tolerance over multi-administrative domains (administration scalability problems) and invented mechanisms to cope with selfish members, in addition to arbitrary faulty members.

Secret Sharing and Threshold Cryptography

Another aspect of intrusion tolerance is to protect confidential information (e.g., security keys) even if some replicas have been penetrated (Deswarte et al., 1991). If all the secrets are maintained by a single process, an adversary may obtain these secrets by compromising the process. To defend against such an attack, each secret is divided into multiple shares and each share is stored in a separate process. To obtain the secret, an adversary must now break into a significant number of processes. This is the basic objective of secret sharing.

A popular secret sharing scheme is the (k, n) threshold scheme, where n is the total number of shares and k is the minimum number of shares needed to reconstruct the secret. No useful information can be obtained as long as the number of shares collected is less than k , the threshold. This scheme is first proposed by Shamir (1979) and implemented using polynomial interpolation. In this scheme, each share is of similar size to the original secret and shares can be dynamically added or deleted.

The (k, n) threshold scheme is quite expensive computationally and space-wise. Therefore, they are used only to protect the most crucial secret such as security keys. It might not be practical

to apply them to file systems or databases. Consequently, a more cost effective scheme, called Fragmentation-Replication-Scattering (FRS), is proposed (Deswarte et al., 1991). It was initially designed to provide intrusion tolerance for file systems and was later extended to object-based systems (Fabre & Randell, 1992). The FRS scheme involves three steps. First, a file is partitioned into many smaller pieces. (To enhance the confidentiality, the file can be encrypted prior to the fragmentation step.) Second, each piece is replicated. Finally, the pieces are distributed pseudo-randomly according to some algorithm to the storage sites. The fragmentation and scattering protect data confidentiality against intrusion attacks because to obtain the file, an adversary must first find out the locations of the fragments belonging to the file and then penetrate all the sites that store the fragments. The replication protects the availability of the file so that even if some pieces are destroyed by an adversary, there are enough copies left to reconstruct the original file.

Despite the elegance of the secret sharing schemes, the secret must be reconstructed before it can be used. This poses a security threat because if the process that performs this task is compromised, the secret may be exposed. This prompted the development of threshold cryptography (Desmedt & Frankel, 1989). In threshold cryptography, security operations such as encryption, decryption, signature generation and verification can be performed by a group of processes without reconstructing the shared secret. Threshold cryptography has been applied primarily to public key based security services by sharing the private key among a group of processes (Zhou et al., 2002). The shares can be proactively updated to further enhance the security. By sharing the private key, each process can produce a partial signature. If a client obtains enough number of partial signatures, it can compute the complete signature. During this process, the private key is never reconstructed.

Protecting Both Availability and Confidentiality

Byzantine fault tolerance ensures service high availability, but it does not protect data confidentiality against intrusions. Threshold cryptography guarantees both confidentiality and high availability of some security operations, but not general services one might use. All secret sharing schemes require the reconstruction of the secret at a trusted site, which may be vulnerable to intrusion attacks.

COCA (Zhou et al., 2002) is the first attempt to integrate a Byzantine quorum system with threshold cryptography in the context of a certificate authority (CA) service. In COCA, the most critical state, i.e., the service private key (used to generate signatures for the certificates issued to clients) is shared among the replicas to prevent an adversary from stealing it. There are other states in a CA service, such as the certificate issued to the clients. A client can query and update the certificate information through the CA services. The high availability of the CA services is provided by the group of CA replicas. To enhance failure resiliency, the replicas are periodically restarted proactively with a correct binary image and the latest state collected from other correct replicas. The server keys (used to communicate securely among the replicas) are also periodically refreshed.

FUTURE TRENDS

Even though there is moderate success in applying intrusion tolerance techniques to a few specific applications, it remains to be seen how to introduce intrusion tolerance to other types of information systems, such as credit card processing systems, online banking systems, and e-commerce systems. The lack of effective solutions has left many mission critical systems vulnerable. This is evidenced by the increasingly frequent reports of high impact security breaches that resulted in massive disclosure of confidential information (Baker et al., 2011), such as the break-in of CardSystems

Solutions, which exposed the confidential data of more than 40 million credit card holders (Dash & Zelle, 2005), the Veteran Affairs incident, which has caused the potential loss of personal data of more than 26.5 million veterans to the hands of adversaries (Dunham, 2006), and recently the Sony PlayStation online network break, which led to exposure of personal data of over 77 million user accounts (Baker & Finkle, 2011).

There are many open issues to be resolved before we see widespread adoption of intrusion tolerance techniques. The most interesting research problem seems to be the design of a systematic methodology that allows direct operation on the shared secret that is dispersed among a number of processes. This will eliminate the vulnerability introduced by relying on a trusted process to reconstruct the secret. Another urgent issue is how to address replica non-determinism problem, especially that caused by multithreading. Practical information systems are very complicated and contain extensive non-deterministic operations. Unfortunately, all Byzantine fault tolerance strategies require deterministic execution of replicas. Even though the non-determinism resulted from a replica's accessing of some local resources (such as clock values and file descriptors) can be easily controlled if the access pattern is known in advance (Yin et al., 2003), there is no straightforward solution to render a multithreaded application deterministic without significantly impacting the application's performance and correctness (Zhao, 2005). Recently, we proposed a drastically different architecture to avoid replicating execution, which would eliminate the need for controlling the replica nondeterminism (Zhao, 2008).

Furthermore, intrusion tolerance favors design diversity to avoid common vulnerabilities among the replicas. N-version programming was proposed as a potential solution by Chen and Avizienis (1978). However, it might not be an economically viable solution due to its heavy software development cost. Alternative, less costly solutions are needed to diversify the

replica implementations. Code randomization appears to be a good approach to achieve replica diversity (Forrest, 1997).

Intrusion tolerance design does not conflict with the effort of intrusion prevention and intrusion detection (Verissimo et al., 2003). In fact, they are all indispensable techniques for building secure and dependable systems. Without applying good intrusion prevention techniques, the application would contain too many vulnerabilities for the replication strategy to take effect. Similarly, intrusion detection plays an essential role in intrusion tolerant systems. To remove a faulty replica and to recover it subsequently, the fault must be detected as quickly as possible. Intrusion detection also helps deter future intrusion attacks if there is enough information logged that can be used to prosecute the intruders (Dunlap et al., 2002).

CONCLUSION

We believe that the research and development of intrusion tolerant systems will gain more momentum as more and more services are offered online. The expectation of such services is high, considering their essential roles in everyday operations of businesses and individuals as well. The impact of service unavailability and security breaches will only be more serious. In this chapter, we have surveyed the state of the art techniques for building intrusion tolerant systems. We also illustrated a few most urgent open issues for future research. Finally, we pointed out that to build secure and dependable systems, we need a concerted effort in intrusion prevention, intrusion detection, and intrusion tolerance.

KEY TERMS AND DEFINITIONS

Byzantine Fault Tolerance: A replication-based technique used to ensure high availability of an application subject to Byzantine fault.

Byzantine Fault: It is used to model arbitrary fault. A Byzantine faulty process might send conflicting information to other processes to prevent them from reaching an agreement.

Byzantine Quorum System: The system offers read and write services to its clients on a set of replicated data items. A read operation retrieves data from a quorum of correct replicas and a write operation applies the update to a quorum of correct replicas. Any two quorums must overlap by at least one correct replica.

Fragmentation Redundancy Scattering: A secret sharing scheme that involves the following three steps: fragmenting a file, replicating each fragment, and distributing the replicated fragments to different storage sites.

Intrusion Tolerance: It refers to the capability of maintaining the system availability and integrity despite malicious attacks.

(k, n) Threshold Scheme: A secret is divided into n shares. To reconstruct the secret, at least k shares are needed. No useful information can be obtained from k-1 shares.

Replica Consistency: The states of the replicas of an application should remain to be identical at the end of the processing of each request. Replica consistency is necessary to mask a fault in some replicas.

Threshold Cryptography: Security operations such as encryption, decryption, signature generation and verification can be performed by a group of processes without reconstructing the shared secret. Threshold cryptography utilizes (k, n) threshold schemes internally.

New Perspectives of Pattern Recognition for Automatic Credit Card Fraud Detection

INTRODUCTION

The automatic detection of frauds in financial operations using credit cards is a challenge issue that has been increasingly studied. The rapid expansion of information and communication technologies has expanded the potential to emulate legitimate operations by fraudsters. The solution to that problem has to be able to be adaptive since the behavior of frauds is changing constantly in time; to handle the detection in data with a very small ratio of fraud amount to legitimate operations, e.g., $5e-5$; and accomplish operation requirements of very low false alarm ratios in real-time processing. Thus, several approaches have been proposed from pattern recognition and machine learning areas.

Main issues related with the problem of automatic credit card fraud detection (ACCFD) and proposed solutions are discussed from theoretical and practical standpoints. The perspective of detection analyses from receiving operating characteristic (ROC) curves and business key performance indicators (KPI) are jointly analyzed (Girgenti & Hedley, 2011) (Wells, 2011) (Montague, 2010). Therefore, a new conceptual framework for ACCFD considering modern techniques such as decision fusion and surrogate data is outlined. There are only a few references from the research field

of signal processing for ACCFD, see for instance (Salazar, Safont, Soriano, & Vergara, 2012).

A case of study that combines different proportions of real and surrogate data is included. Several scenarios considering different single and combined methods are considered. ROC and KPI curves are analyzed bearing in mind numeric and operational requirements. The sensitivity of the methods to different proportions of fraud/legitimate ratios is tested. Thus, limitations and advantages of the studied methods are demonstrated.

BACKGROUND

Cyber-security and privacy have become very important subjects of research in recent years. This research spans many different fields, such as: security in the physical layer of wireless communications (Poor, 2012)); database security (Sankar, Rajagopalan, & Poor, 2013); distributed systems (Pawar, El Rouayheb, & Ramchandran, 2011); and biometrics (Lifeng, Ho, & Poor, 2011). One activity where the security and privacy mechanisms are critical is the e-commerce by using credit cards. This application features a massive volume of on-line transactions that are continuously exposed to frauds. Fraud detection

Figure 1. Outline of the signal processing procedure

in credit card transactions is a critical problem affecting large financial companies and involving annually loss of billions of dollars (Bhattacharyya, Jha, Tharakunnel, & Westland, 2011).

Basically two strategies can be raised. The first consists of defining the problem as one-class classification, and thus, characterizing the largest data population (the legitimate transactions) and considering all the data with different characteristics as outliers (Hodge & Austin, 2004) (Tax & Duin, 2001). The second strategy is to define the problem as a two-class classification characterizing legitimate and fraudulent transaction data. We have concentrated in this later detection approach which takes full advantage of the available labeled data.

There is extensive literature that reviews and provides taxonomies and comparisons about the large number of ACCFD methods that have been developed during the last two decades (e.g., (Danas, 2015)). However, only few of these references are from the research field of signal processing. The particular characteristics of ACCFD make this a challenging problem for signal processing algorithms (Salazar, Safont, Soriano, & Vergara, 2012). Optimum design of the algorithms depends on the detection models employed to estimate the multidimensional joint distribution of the random variables underlying the data.

Figure 1 shows an outline of the proposed signal processing procedure. The multivariate surrogate data is obtained following the methods explained in (Salazar, Safont, & Vergara, Surrogate techniques for testing fraud detection algorithms in credit card operations, 2014). The pre-processing step consists of applying principal component analysis (PCA) to reduce dimensionality of the data preserving 95% of data variance.

SURROGATE DATA

Bank enterprises collect large amount of historical records corresponding to millions of credit cards operations, but, unfortunately, only a small portion, if any, is open access. This is because, e.g., the records include confidential customer data and banks are afraid of public quantitative evidence of existing fraud operations (Bhattacharyya, Jha, Tharakunnel, & Westland, 2011). A solution is to generate synthetic records which replicate as much as possible the behavior of the real data. Surrogate techniques give an approach to this problem. Surrogates algorithms have been extensively used to detect the possible presence of non-linearities in a given time series realization. Basically, surrogate replicas of the original data are generated trying to preserve the correlation (second-order statistic) and amplitude distribution (first-order

statistic). These replicas are generated in such a form that linearity applies. Then some statistics for detecting possible presence of non linearities are computed from both the surrogate replicas and the original data. If significant differences are given, then existence of non-linearity is decided (Prichard & Theiler, 1994).

The main idea of surrogate techniques is to synthesize new stationary data by randomization in the Fourier domain. For multivariate series, cross-correlation among the variables should be conserved. The randomization in the Fourier domain is chosen so that the differences of phase between components stay the same. Let $X(n)$ be a multivariate series with M components ($x_j(n)$ with $n=0, \dots, N-1$ being its j -th component). For initialization, the Fourier transform of each component can be computed:

$$(Fx_j)(f) = \sum_{n=0}^{N-1} x_j(n) e^{-i2\pi \frac{nf}{N}} = Ax_j(f) e^{i\psi_{x_j}(f)} \quad (1)$$

A classical multivariate surrogate can be computed using the following expression:

$$S(n) = [s_1(n), \dots, s_M(n)]^T, \quad (2)$$

$$s_j(n) = \frac{1}{N} \sum_{f=0}^{N-1} Ax_j(f) e^{i(\psi_{x_j}(f) + \Theta(f))} e^{-i2\pi \frac{nf}{N}},$$

where $\Theta(f)$ is a random phase i.i.d. uniform in $[0, 2\pi]$.

However the algorithm of (1) does not impose any constraint to the surrogates that should be restricted to have the same marginal distributions and covariance as the original series (variables). The iterative IAAFT (Iteratively Amplitude Adjusted Fourier Transform) algorithm that projects on the two constraints (the covariance function expressed in the Fourier domain and the prescribed marginal distributions was proposed in (Schreiber & Schmitz, 2000). We applied a new extension of IAAFT algorithm considered in (Borgnat, Abry, & Flandrin, 2012) using a reduced set of real credit

card data to generate surrogate multivariate series of credit card data transactions.

SCORES AND LIKELIHOOD RATIO: A SIGNAL PROCESSING PERSPECTIVE FOR ACCFD

Detection of credit card frauds may be approached from a signal processing perspective. It is comparable to the classical problem of detecting signals in a noise background. The “signal presence” hypothesis (H_1) would be equivalent to “fraud presence”, meanwhile “absence of signal” hypothesis (H_0) would correspond to “absence of fraud”. In both cases hypothesis H_1 has much lower a priori probability than hypothesis H_0 , hence Neyman-Pearson criterion is the most appropriate. Implementation of a Neyman-Pearson

detector is made by the test $\Lambda(\mathbf{x}) = \frac{f(\mathbf{x} / H_1)}{f(\mathbf{x} / H_0)} \underset{H_0}{\overset{H_1}{>}} \lambda$,

where $f(\mathbf{x} / H_i)$ is the probability density of the observation vector $\mathbf{x}$ conditioned to hypothesis H_i , and λ is a threshold selected to fit an acceptable probability of false alarm (PFA). $\Lambda(\mathbf{x})$ is the likelihood ratio (LR) and its computation is the essential signal processing required to implement the optimum detector. Determination of LR mainly depends on the assumed models about the signal and noise. Different optimum detectors may be designed assuming multivariate Gaussian noise and different amount of knowledge about the signal, e.g., matched filter, subspace matched filter, and energy detector.

Similarly, the usual test in fraud detection is of the form $s(\mathbf{x}) \underset{H_0}{\overset{H_1}{>}} t$, where $s(\mathbf{x})$ is a score or

qualification between 0 and 1, assigned to the transaction under analysis. The higher the value $s(\mathbf{x})$, the higher the probability of a fraudulent transaction. The threshold t filters the transactions that would be passed to the human operator. Actually, the daily number of false positive frauds

which the human operators can manage imposes a limit in the PFA in much the same manner that it happens in other areas like radar signal detection. For those filtered transaction, the score $s(\mathbf{x})$ is part of the information taken into account by the operator to arrive to a final decision about authorization.

A natural candidate for $s(\mathbf{x})$ is $P(H_1/\mathbf{x})$, the “a posteriori” probability of having a fraud conditioned to the observation. It is straightforward to show the relation between $s(\mathbf{x})$ and $\Lambda(\mathbf{x})$ by using the Bayes theorem:

$$\begin{aligned} s(\mathbf{x}) &= P(H_1 / \mathbf{x}) = \frac{f(\mathbf{x} / H_1)P(H_1)}{f(\mathbf{x})} = \\ &= \frac{f(\mathbf{x} / H_1)P(H_1)}{f(\mathbf{x} / H_1)P(H_1) + f(\mathbf{x} / H_0)P(H_0)} = \\ &= \frac{\Lambda(\mathbf{x})}{\Lambda(\mathbf{x}) + \frac{P(H_0)}{P(H_1)}} \Leftrightarrow \Lambda(\mathbf{x}) = \frac{s(\mathbf{x}) \frac{P(H_0)}{P(H_1)}}{1 - s(\mathbf{x})} \end{aligned} \quad (3)$$

So we see the LR is implicitly considered given a scoring function, and, vice versa, a score value may be computed from the LR. In consequence, a test based in comparing the score (computed as the a posteriori probability of H_1) with a threshold is an LR test:

$$s(\mathbf{x}) \underset{H_0}{\overset{H_1}{>}} t \quad \Leftrightarrow \quad \Lambda(\mathbf{x}) \underset{H_0}{\overset{H_1}{>}} \frac{t}{1-t} \frac{P(H_0)}{P(H_1)} \quad (4)$$

Notice that the observation vector $\mathbf{x}$ will be formed by a set of heterogeneous features such as money amount, commerce code, country code, operation date and so on, that are extracted directly from the records. Besides, taking into account that the behavior of fraudsters normally emulates regular customer behavior in directly measured features; additional indirect features can be estimated to highlight differences (e.g., transaction velocity, transaction acceleration,

and country commuting). Thus, it is not easy to find parametric models for the statistical distributions of the observations under fraud and no fraud conditions. Hence, deriving optimum sufficient statistics or implementing generalized likelihood ratio tests (GLRT) are not practical options. However, it is usual that sets of training observations for both hypotheses are available, so that supervised learning of the LR or of a score function is possible. This is an advantage in comparison with signal detection, where sets of the expected signals are difficult to measure or to generate: it is difficult to learn $f(\mathbf{x} / H_1)$ from observation samples.

Other differences between these conceptually equivalent problems are in the type of performance measures. In signal detection the Receiving Operating Characteristic (ROC) curves (probability of detection, PD, as function of probability of false alarm, PFA) are the most usual. In addition, the dependence of PD on the signal-to-noise-ratio (SNR) for a given PFA, is very familiar. SNR is not a practical concept in fraud detection, as the presence of a fraud modifies the distribution of $\mathbf{x}$ in an arbitrary and unpredictable form rather than a simple change in energy. Moreover, PD is a relative measure of good performance as the final goal is to save money, i.e., it is better to detect one fraud involving a lot of money than many frauds of small amounts of money. Thus the Value Detection Rate (VDR) defined as the percentage of saved money is usually preferred. In addition, the Account False to Positive Rate (AFPR) defined in (5) is considered as a sample estimate of the average number of useless interventions in non-fraudulent operations produced for every detected fraud.

$$\begin{aligned} AFPR &= \frac{\text{True positives} + \text{False positives}}{\text{True positives}} = \\ &= 1 + \frac{\text{False positives}}{\text{True positives}} \end{aligned} \quad (5)$$

In conclusion, there are clear similarities between signal and fraud detection, but some differences exist, positioning the fraud problem somewhere in between signal processing and pattern recognition areas.

FUSION OF SCORES

Fraud detection is a difficult problem due to the arbitrary and variant nature of the statistical models under both hypotheses. This imposes the need of adaptive supervised learning of reasonable (probably non-optimum) detectors from datasets of millions of labeled transactions. The extremely large amount of available legitimate operations in comparison with the moderate number of confirmed frauds introduces an additional difficulty for a balanced learning of the models under both hypotheses. All this suggests that approaches based on deriving one “sophisticated” detector, having many degrees of freedom and/or parameters to be dynamically and continuously learned, will not be an appropriate approach. Instead, the idea of combining or fusing complementary robust detectors is tempting (some formal ideas about this intuitive concept emanates from the so-called evidence theory (Shafer, 1976)). Fusion of detectors has been considered since long time ago in different areas and under different terminologies: multimodal fusion (Atrey, Hossain, El Saddik, & Kankanhalli, 2010), mixture of experts (Yuksel, Wilson, & Gader, 2012) and classifier combiners (Kittler, Hatef, Duin, & Matas, 1998), to mention a few, but there is convenient to focus into the fraud detection context.

Let us assume that N different detectors are designed to detect possible frauds. Different designs may be the result of using different training sets on the same detector structure, of using different detector structures or both. In any case, every detector i produces a score s_i and we must find a fusion function to compute a final score s_f . Then, finding the optimum fusion function is

a design objective. This can be approached in a similar manner to the original problem of determining one score from the observation vector $\mathbf{x}$. We may consider that the vector of individual scores $\mathbf{s} = [s_1 \dots s_N]^T$ is a new observation vector, and then s_f may be computed from the LR of scores

$$s_f(\mathbf{s}) = \frac{\Lambda(\mathbf{s})}{\Lambda(\mathbf{s}) + \frac{P(H_0)}{P(H_1)}} \quad \Lambda(\mathbf{s}) = \frac{f(\mathbf{s} / H_1)}{f(\mathbf{s} / H_0)} \quad (6)$$

So, ultimately, the optimum fusion function depends on the joint probability densities functions of the scores under both hypotheses, $f(\mathbf{s} / H_1)$ and $f(\mathbf{s} / H_0)$. If we assume that the scores are independent and identically distributed random variables then (6) can be expressed as

$$s_f(\mathbf{s}) = \frac{\frac{f(s_1 / H_1) \dots f(s_N / H_1)}{f(s_1 / H_0) \dots f(s_N / H_0)}}{\frac{f(s_1 / H_1) \dots f(s_N / H_1)}{f(s_1 / H_0) \dots f(s_N / H_0)} + \frac{P(H_0)}{P(H_1)}} \quad (7)$$

In that case non-parametric estimates of the marginals can be obtained from training set of scores and introduced in the computation of the final score (plug-in methods, (Jain A. K., 2000)). But the fusion problem becomes more complicated if statistical independence among the individual scores cannot be assumed (Vergara, Soriano, Safont, & Salazar, 2016). Actually, presence of dependence can be expected if all the detectors share the same input $\mathbf{x}$. Unless Gaussianity could be assumed, capturing the dependence of multivariate random variables is not an easy problem. Gaussian and Non-Gaussian Mixtures Models are possible options (Tzikas & Likas, 2008) (Salazar, Vergara, Serrano, & Igual, 2010), they require the estimation of many parameters and the determination of the best number of mixture components. Another alterna-

tive is based on the use of copulas. Copula methodology has been used during years in econometrics, although it is only recently considered in the signal processing community (Iyengar, Varshney, & Damarla, 2011). The multivariate probability density function is factorized in the marginals and a copula function which captures dependence. The copula function is the multidimensional probability density function of uniform variables derived from the original dependent variables. A family of parametric functions exists having the required copula properties, so that a variety of dependence models are possible. Another option is α -integration (Soriano, Vergara, Ahmed, & Salazar, 2015), which is expressed as

$$s_f(\mathbf{s}) = \begin{cases} \left(\sum_{i=1}^N w_i \cdot s_i^{\frac{1-\alpha}{2}} \right)^{\frac{2}{1-\alpha}}, & \alpha \neq 1 \\ \exp \left(\sum_{i=1}^N w_i \cdot \log(s_i) \right), & \alpha = 1 \end{cases} \quad (8)$$

First, every score is modified by a nonlinear function controlled by the α parameter. Then, a weighted mean of the modified scores is computed, and the nonlinear inverse function is finally applied to the weighted mean. The α parameter and the weights w_i $i=1, \dots, N$ can be estimated so that a predefined cost function is minimized. One interesting aspect of α -integration is that some simple cases are included for particular values of α and w_i . Thus, assuming that $w_i = 1/N$, we see that $\alpha = -1, 1, 3$ respectively renders the arithmetic mean, the geometric mean and the harmonic mean. Similarly, $\alpha = \infty / -\infty$ is equivalent to compute the minimum/maximum.

The proposed signal processing procedure was applied using a set of real data provided by a large financial company. These data were combined with surrogate data following the methods described in (Salazar, Safont, & Vergara, Surrogate techniques for testing fraud detection algorithms in credit card operations, 2014). Thus, a total dataset of 37.000.000 transactions were available (90%

surrogate). These dataset correspond to about 3 million credit cards with a total of 2005 fraudulent transactions from 682 credit cards. The proportion between fraudulent and legitimate transactions is different from the real proportion, but it is small enough for evaluating the methods. This dataset was divided 5% for training stage and 95% for testing stage. Figure 2 shows the distribution of the data in the first two components space estimated by PCA. It can be seen that the fraud data are crowded together the genuine data making difficult the separation of the two kinds of data. Although the genuine data have been sub-sampled 100 times, it can be seen the high disproportion between the two kinds of data.

Seven different representative detectors were selected. Three of them are individual detectors selected from generally applied methods: Linear Discriminant Analysis (LDA), Quadratic Discriminant Analysis (QDA) and NonGaussian Mixture Models (NGM) (Salazar, On Statistical Pattern Recognition in Independent Component Analysis Mixture Modelling, 2013). Two more were considered because they have been previously used in the ACCFD problem: Random Forest (RF) and Support Vector Machines (SVM). Finally two fusion methods were applied. The first is α -integration (α -INT). The second fusion method was based on the use of a Gaussian copula (COP). Several experiments show that SVM and RF did not contribute to improve fused results, so the final methods included in the fusion step were LDA, QDA and NGM.

Figure 3 shows the ROC curves corresponding to transactions summarized by cards for the seven methods. Actually, the detectors are applied to every transaction, but once a transaction is detected as fraudulent the associated card is considered fraudulent in the observed period of analysis. Thus ROC curves of transactions may differ from ROC curves of cards, being these latter more significant in the ACCFD context. In Figure 3 we only represent the acceptable margins for the PFA [0, 0.04]. We can see that PDs under 0.5 are obtained; this can be unacceptable in other

Figure 2. Scatter plot of the data in two component space. Localization of fraud data is highlighted.

applications but are very significant in ACCFD as this can potentially lead to saving big amount of money. Finally, we deduce from Figure 3 the following main conclusions. First, LDA is clearly below the rest of methods, thus suggesting that Gaussian models are not appropriate in this case. Second, fusion methods improve the individual detectors, especially for the lowest values of PFA.

KPI CURVES

KPI are estimated after processing in order to evaluate the results from the business operational perspective. They provide different information than the ROC curves because they take into account not only the transactions themselves, but also variables such as grouping of transactions using card number; the amount of each transaction; and the period of time until the fraud is detected (VDR and AFPR were defined above):

- **ADR:** Account Detection Rate, the percentage of detected fraudulent cards.

- **ADT:** Average Detection Time, the average amount of fraudulent transactions on the same card required for detecting its fraudulent use.

Figure 4 shows the results obtained with KPI to be compared with Figure 3. It represents VDR as function of the normalized number of daily alerts (number of daily alerts divided by the total number of processed cards in a day). In general, results are similar but a significant difference is present, in this case, α -INT performs better than COP when VDR instead of PD is computed. There are several discussions that can be made from KPI results, but they are outside the scope of this work.

SURROGATE AND FRAUD/LEGITIMATE RATIOS

Figures 2 and 3 show results of the surrogate algorithm for legitimate and fraud operations, respectively. Figure 1a shows 500 samples of the surrogate data for the first eight components. Figure 1b shows the histogram of the eight com-

Figure 3. ROC estimated from the results of detection methods

Figure 4. VDR with respect to normalized alerts per day estimated from detection methods

Figure 5. Results of surrogate data from legitimate operations

ponents in surrogate data, in black bars, with the histogram of the legitimate operations superimposed in red. Note, that those distributions are non-Gaussians. Figure 1c compares the autocorrelations of each surrogate component (in blue) with the corresponding autocorrelation of the legitimate data (in red). Finally, Figure 1d shows the cross-correlations of the first component with the other components (first seven rows) and the cross-correlation of the second component with the third component (eighth row). The cross-correlations of the surrogate data are shown in blue, and the cross-correlations of the legitimate data are shown in red. It can be seen that surrogate

legitimate operations were very close to the real legitimate operations from standpoints of marginal distributions of the components and autocorrelation and cross-correlations between variables.

Figure 7a shows the joint probability density functions (pdf) of real (blue) and surrogate (red) legitimate operations. Similarly, joint pdfs for fraud operations are shown in Figure 7b. Although the joint pdfs are calculated for all 8 components at once, they are shown in slices of two components to make the result more readable. The results in Figure 7 show that the surrogate data had very similar joint pdf to that of real legitimate data. The peaks of the pdf for the surrogates were located at

Figure 6. Results of surrogate data from fraud operations

Figure 7. Joint distribution of a) legitimate and b) fraud operations

the same positions as the peaks of the pdf for the true data, and the shapes of both pdfs were very close in all cases. The pdf of the surrogates were more diffuse (i.e. less discrete), which might be caused by the amount of non-stationarity in the legitimate operations.

Similarity of the surrogates and the real operations was also tested by performing ACCFD using the method α - INT explained above. A certain amount of randomly-selected operations were replaced with surrogate operations and the

detection was repeated. The amount of replaced operations was changed from 0% (only true operations) to 50%, 75%, and 100% (only surrogate operations). The obtained ROC curves are shown in Figure 8 showing that the curves are similar in all cases even for low false alarm values (Figure 8b). There are some differences in value for very low amounts of FPR. In all cases, the lower the amount of surrogate operations, the closer the ROC became to that of the real operations (all the curves were very close for FPR above 0.06).

Figure 8. ROC curves for different percentages of surrogate data: a) complete curves; b) zoom in a zoom of interest

Figure 9. ROC curves for different proportions of fraud/legitimate operations obtained by different methods

Figure 9 shows the results of applying different algorithms for ACCFD changing the fraud/legitimate ratio. It can be seen that the performance decreases the ratio decreases with α -INT method obtaining best results for all ratios. Furthermore, α -INT performance shows robustness at very-low false alarm values. Thus, exploiting complementarities of basic detectors seems to be immune for the fusion method.

FUTURE RESEARCH DIRECTIONS

Improvement of fusion techniques to take full advantage of complementarities among detectors is still required. A challenging issue is to consider in the fusion method that the behavior of the detectors for transaction scoring is not regular for the whole dataset. Also changing fraud dynamics might continuously distorts the complementarities among the detectors making tighter the design of an optimum fusion method. Methods that incorporate prediction and temporal dependence should be devised for ACCFD.

Besides, the combination of different kinds of general detectors presented here, there are other alternatives that can be explored. Several versions of a kind of detector that are trained in different

ways can be combined, for instance, using different versions of the data, searching specialized decision trees for each of the features, etc. Some examples of that kind of methods are boosting, bagging, and mixtures of experts. One of the critical issues for these ensemble approaches is to adequately handle with the so-called bias-variance tradeoff. Small bias indicates that training data has been learned well (small error of prediction) and small variance indicates capability of generalization, i.e., unobserved data might be predicted with small error. The problem consists of a low variance causes a low bias and vice-versa.

Technological constraints and prospective arising from big data context including data storage, privacy and security, and time processing issues are also subjects for future research.

CONCLUSION

We have presented a new application having unquestionable interest for the signal processing community. Some similarities and differences with classical detection problems in the signal processing area have been emphasized. Then it has been considered the use of fusion as a powerful technique to derive algorithms having

reasonable performance to solve this very complex problem. Experimental results using large real and surrogate datasets have been showed, where the improvements of using fusion of scores have been illustrated. Different well-known methods were compared with the new approaches. The detection results obtained for different mixtures of real and surrogate data were comparable under real requirements of very low false alarm.

An important aspect to have in mind is the context. Thus, arriving to probabilities of detection of 40% (to give a number) may be useless in other areas like radar detection, but can be extremely significant in credit card fraud detection, as it could imply a big amount of money saving. Also the usual figures of merit should be replaced by the KPI. In this sense, much work remains to arrive to methods suited to “modified cost functions”, which better reflect the actual optimization to be reached, or to practical methods that can select the best detectors for a simultaneous fitting of the KPI.

KEY TERMS AND DEFINITIONS

Classifier: A computational method that can be trained using known labeled data for predicting the label of unlabeled data. If there's only two

labels (also called classes), the method is called “detector”.

Fusion of Scores: A process for efficient combination of a set of scores or probabilistic grades granted by a set of detectors/classifiers. Evaluation of combination performance depends on the application objectives.

KPI: Key performance indicator is an index that defines the performance of a process. In the case of ACCFD, roughly, the set of KPIs serves to translate ROC results into business terms.

Pattern Recognition: Automatic process of extracting, representing, and splitting conspicuous characteristics from a dataset to produce several subsets that can be associated with concepts normally accepted by humans.

Receiving Operating Characteristic (ROC) Curve: A numeric tool for the evaluation of a detection process that implements comparison in a coordinate plane of probability of detection and probability of false alarm at different operating points from 0 to 1.

Surrogate Data: Data that are computationally generated that behave with statistical features similar to that of real data.

Privacy, Algorithmic Discrimination, and the Internet of Things

University of Hawaii at Manoa, USA

INTRODUCTION

The Internet of Things (IoT) is a paradigm encompassing a wide range of developments that enable everyday objects to be tagged and uniquely identified over the Internet. Although there is no single definition for the Internet of Things, competing visions agree that it relates to the integration of the physical world with the virtual world, with any object having the potential to be connected to the Internet via short-range wireless technologies, such as radio frequency identification (RFID), near field communication (NFC), or Wireless Sensor Networks (WSNs). This merging of the physical and virtual worlds will “enable the Internet to reach out into the real world of physical objects” (Internet of Things Conference Organizing Committee, 2010). Further, it will allow increased instrumentation, tracking and measurement of the natural world, enabling analytic tools to enhance business management processes and offer citizens increased convenience and safety (Uckelmann, Harrison, & Michahelles, 2010).

The IoT is imagined as a “backbone for ubiquitous computing, enabling smart environments to recognize and identify objects, and retrieve information from the Internet to facilitate their adaptive functionality” (Weber & Weber, 2010, p. 1). In this regard, the IoT is an emerging global architecture that will enable enhanced machine intelligence to automate the exchange of goods and services. In addition to improving supply chain management, this integration of tags and sensor networks will also be employed in diverse application scenarios, including smart appliances

and smart homes, disaster warning, structural engineering, farming, and in-vivo health applications (Atzori, Iera, & Morabito, 2010). This chapter will introduce the Internet of Things, address its definition and related concepts, outline anticipated application areas, highlight challenges, and discuss privacy and surveillance concerns.

BACKGROUND

Related Areas

Current research agendas focus on the IoT ecosystem—networks of physical objects embedded with the ability to sense, and sometimes act upon, their environment, as well as related communication, applications, and data analytics (Gartner, 2014). The IoT is often mentioned in relation to other, overlapping research paradigms, particularly Ubiquitous Computing, Pervasive Computing, and Ambient Intelligence, research agendas that address the integration of myriad, heterogeneous objects into the everyday environment. Weiser’s (1991) vision of Ubiquitous Computing emerged in the late 1980s and emphasized the potential of multiple computers per person, in a variety of forms, to activate the physical environment and make computational intelligence an extension of human activity. Ubiquitous Computing research is distinguished by its human-centered focus and has increasingly addressed interaction contexts (Abowd, Ebling, Hunt, Lei, & Gellersen, 2002). The related concept of Pervasive Computing (Hoffnagle, 1999) emerged as a corporate vision

at IBM during the late 1990s. This agenda has focused on the technical systems required to embed numerous, networked devices throughout the environment. Over time, the two research communities have overlapped, and the two leading conferences, ACM's Pervasive and UbiComp, merged in 2013. Ambient Intelligence research has been guided by the European Union's Fifth Framework Programme (Information Society Technologies, 1998-2002) and focuses on embedded devices, particularly those in smart homes, which are context-sensitive and tailored towards personal needs. While the IoT overlaps technical developments in these related areas, it is distinguished by several concepts. These include 1) goals for an architecture that provides billions, or trillions, of heterogeneous objects with unique identifiers that allow them to interact over a global network; and 2) an emphasis on machine-to-machine (M2M) communication. Although all of these paradigms tend to focus on near-term visions of potential future environments (Dourish & Bell, 2011), the IoT is already manifest in various ways today.

Origin and Evolution of the Concept

Kevin Ashton is credited with the first use of the phrase "Internet of Things" in 1999. He focuses on the potential of M2M intelligence to capture real-time data about the physical world and use it without direct human oversight (Ashton, 2009), stating that the goals of IoT research and development focus on endowing computers

with their own means of gathering information, so they can see, hear and smell the world for themselves, in all its random glory. RFID and sensor technology enable computers to observe, identify and understand the world—without the limitations of human-entered data. (Ashton, 2009, para. 5)

Although the concept arose in the context of supply chain management, he emphasizes that the IoT now applies to nearly any aspect of the physical world.

Since Ashton's first use of the phrase, the IoT has been associated with a wide variety of academic, government, and corporate research projects. An early and substantial influence was the Massachusetts Institute of Technology's Auto-ID Center, which was formed in 1999 to create an RFID-based IoT architecture for global supply-chain management. In 2003, the Auto-ID Center closed, and EPCglobal took over its commercial work. This effort spun off into the Auto-ID Labs, seven academic research labs that focus on building a global infrastructure using RFID or other short-range, wireless technologies. The Auto-ID Labs developed the Electronic Product Code (EPC), an RFID tag that uniquely identifies a product, and the EPCglobal stack is the de facto standard for retail and consumer goods industries.

Other large-scale efforts include IBM's Smarter Planet strategy initiated in 2008 (IBM, 2008), which has focused on the potential of instrumenting the physical world with tens of billions (perhaps trillions) of interconnected sensors. Here, the IoT is envisioned as a way to fuel economic growth, business and government efficiency, improve physical security, and enhance scientific knowledge. Similarly, HP's Central Nervous System for the Earth (CeNSE) initiative relies on billions of nanoscale sensors to detect vibration and motion (HP, n.d.)

The IoT has also figured prominently in national and international technology policy strategies. Following the International Telecommunication Union's special report on the IoT (International Telecommunication Union, 2005a), the European Union's Directorate, General Information Society and Media shifted concern to the IoT (European Commission, Community Research and Development Information Service, 2012) with its i2010 policy framework for the information society and media (2005-2010). Under its Seventh Framework Programme (FP7), the EU funded the CASAGRAS (Coordination and support action for global RFID-related activities and standardization) program, which has provided a framework for research to aid the European Commission in

navigating international issues related to RFID, in particular the IoT (CASAGRAS, 2009). This project defines the IoT as

A global network infrastructure, linking physical and virtual objects through the exploitation of data capture and communication capabilities. This infrastructure includes existing and evolving Internet and network developments. It will offer specific object-identification, sensor and connection capability as the basis for the development of independent cooperative services and applications. These will be characterised by a high degree of autonomous data capture, event transfer, network connectivity and interoperability. (CASAGRAS, 2009, p.10)

Simultaneously, the industry-driven policy initiative EPoSS (European Technology Platform on Smart Systems Integration) has sought to direct research and innovation needs related the IoT (European Technology Platform on Smart Systems Integration, n.d.).

China is also taking a lead role in IoT research and development. In 2009, Chinese Premier Wen Jiabao announced that IoT will be central to China's coordinated, national strategic development (GSMA, 2015). The IoT appears in China's 12th Five Year Plan, which guides policy from 2011–2015 (Hvistendahl, 2012). This has led to a number of IoT research parks throughout China, including an Internet of Things Center established in Shanghai and the City of Wuxi redesigned as a research and development center.

Components of the Internet of Things

Atzori et al. (2010) argue that the IoT arises from three different, overlapping visions: 1) things-oriented visions focusing on real-world objects embedded with RFID or sensor technologies; 2) Internet-oriented visions; and 3) semantic-oriented visions. The components of each of these are addressed next.

‘Things’ are objects in the natural world that we wish to instrument. Each thing must be connected to a communication device, such as an RFID chip, a sensor, or an actuator. These can be embedded in a variety of objects, including mobile phones, automobiles, home appliances, clothing, or even the human body. In addition to RFID-tagged objects or NFC-embedded smartphones, things may include nanoelectronics, sensors, or other embedded systems that detect, measure, compute, and communicate (Vermesan et al., 2011). Data about these objects can include location-based information, data from the environment that the object is sensing, or other, stored data. According to Vermesan et al. (2011), things are

expected to become active participants in business, information, and social processes where they are enabled to interact and communicate among themselves and with the environment by exchanging data and information “sensed” about the environment, while reacting autonomously to the “real/physical” world events and influencing it by running processes that trigger actions and create services with or without direct human intervention. (p. 10)

These developments will be supported by the emergence of linked data, standards and practices for connecting structured data via the World Wide Web, creating a massive, global data space that can be navigated and processed by machine intelligence (Heath & Bizer, 2011). This will enable the Semantic Web (Berners-Lee, 2000), a web of data that can be processed by machines without human intervention.

Networks are a second area of research concern. The maturity of RFID, NFC, and wireless sensor networks (based on IEEE 802.15.4) is poised to allow the interconnection of various smaller networks to the Internet. However, whereas the Internet relies on the TCP/IP protocol stack for end-to-end transmission, there is no single standard to connect these intranets of objects to the Internet. A variety of communication standards

operating at various layers are in development. To reach a global scale and maximize the interoperability of heterogeneous systems, there is a need for development of flexible, open standards.

Semantic specifications, the third area of interest, are concerned with how to represent, store, organize, and query objects and data. Here, research focuses on the developments of autonomous software agents and semantic standards for machine communication. Vermesan et al. (2011) highlight the need for “ontology-based semantic standards [that] will enable mapping and cross-referencing between them, in order to enable information exchange” (p. 42).

Application Areas

Applications for the IoT are numerous and diverse, addressing tasks such as measuring location, temperature, acceleration, pollution, or chemical components. Data collected from these sensors is expected to enhance resource management in virtually every sector. The following is a list of potential uses:

- **Logistics/Supply Chain Management:** e.g., item tracking (Ashton, 2009); re-stocking; payment systems (Uckelmann & Harrison, 2010; Atzori et al., 2010).
- **Scientific Research:** e.g., remote or small scale experiment monitoring.
- **Health Care/Biomedical:** e.g., ambient sensors for independent living; implantable or edible medical devices (CERP-IoT, 2010).
- **Environment:** e.g., natural disaster prediction, such as flood, fire, earthquake, tsunami warning systems (CERP-IoT, 2010); chemical, and gas leak identification; pollution and temperature monitoring (Hvistendahl, 2012); water potability testing.
- **Security:** e.g., motion-sensitive camera activation; access control; radiation moni-

toring (Ishigaki, Matsumoto, Ichimiya, & Tanaka, 2013); intrusion detection (Khan, Khan, Zaheer, & Khan, 2012).

- **Structural Engineering:** e.g., monitoring and identifying faults in buildings, roads, or bridges (Agrawal & Lal Das, 2011).
- **Food Safety:** e.g., testing (Hvistendahl, 2012) and recall of tainted food (CERP-IoT, 2010).
- **Agriculture:** e.g., monitoring hydration, chemical composition, or soil quality; live-stock tracking (CERP-IoT, 2010).
- **Smart Cities:** Infrastructure monitoring; management of smart grids to govern cost- and resource-efficient use of energy (Khan et al., 2012; Atzori et al., 2010); “Green ICT” to lower environmental impact (Vermesan et al., 2011).
- **Smart Homes:** e.g., automatic lighting and power allocation (CERP-IoT, 2010).
- **Transportation:** Aerospace part authentication (CERP-IoT, 2010); sensor-enabled roads; assisted driving (Atzori et al., 2010).
- **Augmented Reality Maps:** e.g., maps equipped with tags enabling NFC-equipped phones to automatically interact with Web services (Atzori et al., 2010).
- **Social Networking:** e.g., automated updates of information on social networks (Atzori et al., 2010).
- **Transparency of Government Data:** Anti-corruption (Bertot, Jaeger, & Grimes, 2010).

PRIVACY AND THE INTERNET OF THINGS

An estimated Zettabyte (1,000,000,000,000,000,000 bytes) of data will flow over the Internet in 2016 (Cisco, 2014), as much data as in the entire history of the Internet since its creation in 1969. However, threats to privacy introduced by the IoT are not merely related

to the increased magnitude of data collection. The following are unique challenges to privacy in the context of the IoT (Winter, 2013):

1. **Lack of Transparency:** Small components are not necessarily visible. One may not be aware when and where data is being collected (Langheinrich, 2001).
2. **Sheer Number of Objects Monitoring the Environment:** Even under a scheme where one could “opt out” of data sharing, the interface to accomplish this would be unmanageably complex. Similarly, if an individual wishes to deactivate, or temporarily halt, an object’s communication potential, the number of objects might make this difficult.
3. **Novel Data Types:** Billions, or trillions, of everyday objects, even the human body itself, may be equipped with networked sensors. Many novel data types can be collected. For example, a variety of biometric data in aggregate form.
4. **Increased Aggregation of User Data:** As data analytics is increasingly embedded into the core of business and operational functions (Davenport, Barth, & Bean, 2012), there is a strong economic incentive to model user data. Thus, data may be collected indiscriminately for future use.
5. **De-Anonymization of Personal Data:** Data that has been anonymized in order to meet legal requirements can be “re-personalized” via data mining techniques (Schwartz & Solove, 2011; Winter, 2016).
6. **M2M Processing and Communication:** Machine intelligence will be used both to collect and to analyze these data, increasing both the scope and analytic potential of big data analytics.

Unjust Algorithmic Discrimination

Unjust discrimination based on big data analytics is a growing concern (e.g., Custers, 2013, boyd,

Levy, & Marwick, 2014). Various data about our daily lives are being mined to reveal associations or behaviors, leading to potential political or economic discrimination by governments and corporations in the form of offering different services, products, or prices to individuals based on their data profile (Turow, 2012; Winter, 2015). Examples include:

- Insurers are beginning to allocate risk differently (Upturn, 2014). As new forms of price differentiation emerge, risk calculations by insurers will no longer be spread across a large pool of people, leading to higher burdens (e.g., denial of coverage or higher costs) for some.
- In the criminal justice system, data-based risk assessment is now being considered for use at sentencing. The State of Pennsylvania may allow “some offenders considered low risk to get shorter prison sentences than they would otherwise or avoid incarceration entirely. Those deemed high-risk could spend more time behind bars” (Barry-Jester, Casselman, & Goldstein, 2015, para. 4).
- Data gathered via the smart grid might be used to collect personal information. The National Institute of Standards and Technology observed that smart grid data might reveal specific lifestyle information that could be used by insurers or commercial service providers (National Institute of Standards and Technology, 2010).
- Researchers were able to uniquely identify males who had shared personal DNA sequences on Internet genealogy forums based on publicly available data (Gymrek, McGuire, Golan, Halperin, & Erlich, 2013). While in the United States the *Genetic Information Nondiscrimination Act* is intended to prevent abuse of genetic data, the financial incentives for mining these data are immense, and big data ana-

lytics may enable non-protected “proxy” fields (i.e., other patterns or data-based evidence that is not explicitly protected) to be used instead (Barocas & Selbst, 2016).

In 2013, news coverage about the existence of Internet surveillance programs by the United States’ National Security Agency and its partners in other countries was credited for growing public awareness and concern about government surveillance (Pew Research Center for the People and the Press, 2013). This growing concern may cause additional resistance to IoT developments. Further, self-censorship due to privacy concerns may limit citizens’ freedom of access to information or discussion of issues relevant to democratic decision-making.

Challenges for the Internet of Things

The IoT research community is addressing a wide variety of technical and social issues. Overall, key challenges for development of the IoT include:

- Development of a universal architecture based on open, layered standards (Vermesan et al., 2011).
- Network scalability (Uckelmann et al., 2011).
- Integration of non-IP-based things into the network (Uckelmann et al., 2011).
- Design of energy-efficient objects (Atzori et al., 2010).
- Addressing schemes (Vermesan et al., 2011).
- Autonomous agent design (Vermesan et al., 2011).
- Data storage, representation, and querying standards (Vermesan et al., 2011).
- Mobility management (Atzori et al., 2010).
- Creation of large-scale testbeds for real-world experimentation (Gluhak, Krco, Nati, Pfisterer, Mitton, & Razafindralambo, 2011).

- Spectrum efficiency (Khan, Khan, Zaheer, & Khan, 2012).
- Object and network security (Weber, 2010).

Each of these areas presents a set of robust challenges, and *privacy* should be considered throughout the design process and product lifecycle, rather than as an afterthought. Below, solutions and recommendations for this complex problem are outlined.

SOLUTIONS AND RECOMMENDATIONS

There is no single solution to address privacy concerns related to the Internet of Things. A complex and ongoing approach addressing three domains – sociological, technical, and regulatory – is required (International Telecommunication Union, 2005b).

The sociological domain includes public education and ongoing negotiation about acceptable uses in various contexts. Fostering discussion with a broad range of stakeholders at an early stage of IoT development is necessary to ensure that these developments align with community values and goals (Winter, 2008).

The technological domain includes an array of privacy enhancing technologies (PETs). PETs can include software that allows users to set privacy preferences, “hide” from others on the network, or erase traces of activity. Other means include encryption tools, peer-to-peer systems (P2P), or the ability to switch off tags or sensors (Weber & Weber, 2010). All of these approaches have limitations and, due to the scale and heterogeneity of the IoT, do not provide a satisfactory solution to privacy concerns. Cavoukian and Kursawe (2012) argue that privacy must be introduced during the earliest stages of system development. Privacy by design is a design framework with principles that protect personal privacy while

enabling high-quality data collection and analysis. Using the principles in the framework, a variety of systems with diverse goals and contexts can be designed with privacy at the core, rather than as an afterthought.

Because the IoT is a global system, the regulatory domain is particularly complex. Weber and Weber (2010) argue that the time to create legal protections is before major problems arise. Weber (2010) argues that a new privacy approach is required. “The nature of the IoT asks for a heterogeneous and differentiated legal framework that adequately takes into account the globality, verticality, ubiquity and technicity of the IoT” (p. 30). He acknowledges that neither industry self-regulation nor national laws will be sufficient. As Hildner (2006) observes, “Experience demonstrates that legally unenforceable self-regulation will not be a sufficient limitation on RFID’s threat to privacy” (p. 159). On the other hand, omnibus laws (such as those in the European Union) may be difficult to enforce outside of their jurisdiction. Weber (2010) argues for the development of key principles to be set by a transparent, international organization complemented with more detailed regulation originating in the private sector. However, the feasibility of this approach is uncertain. In December, 2013, the United Nations General Assembly adopted a consensus resolution strongly supporting a right to privacy (United Nations News Centre, 2013). The IoT is a complex sociotechnical system comprised of a plurality of actors, networks, institutions, and contexts, and efforts to regulate privacy at an international level may not be sufficient. Instead, we may see global privacy regulations continue at a variety of levels and contexts rather than as a global, coordinated approach.

FUTURE RESEARCH DIRECTIONS

As outlined above, there are a number of critical technical challenges for the Internet of Things,

including issues of network scalability, integration of non-IP-based objects into the network (Uckelmann et al., 2011), standards for data storage, representation, and querying (Vermesan et al., 2011), and spectrum efficiency (Khan, Khan, Zaheer, & Khan, 2012). Further, there is a need for increased focus on security and privacy (Weber, 2010). Focusing on privacy, each of the three domains outlined by the International Telecommunication Union (2005b) – sociological, technical, and regulatory – present fertile areas for research related to privacy and the emerging Internet of Things. Within the sociological domain, research is needed to better understand users’ behaviors and attitudes related to IoT use, particularly in specific contexts of use. Within the technological domain, many aspects of IoT network and object design will benefit from robust security- and privacy-enhancing technologies, especially those that are built into overall system design. Within the regulatory domain, there is a need for development of an internationally-recognized set of key principles related to privacy rights. Research is also required to map and assess the distributions of social benefits and harms related to the IoT in order to determine whether the resulting distributions serve the public good. Further, there is a need for studies that promote a clearer understanding and assessment of privacy regulation at national, regional, and international levels.

CONCLUSION

This chapter introduced the IoT and provided an overview of its main components and various research initiatives that guide its development. The IoT is likely to have many beneficial applications that impact nearly every sector, and a number of these noted in the literature were addressed. Further, key challenges were outlined, including the issues of privacy and unjust algorithmic discrimination. Foresight activities involving a broad range of stakeholders are necessary both

for the formulation of legislation and to inform system design. IoT systems should be designed with privacy in mind from the start.

KEY TERMS AND DEFINITIONS

Ambient Intelligence (AmI): Describes an environment in which many embedded, networked devices exist throughout the environment. Typically, these are tailored towards personal needs and aware of context. This research program is often associated with smart homes. Ambient Intelligence research has been guided by the European Union's Fifth Framework Programme (Information Society Technologies, 1998-2002).

Electronic Product Code (EPC): Is a standard that seeks to provide unique identification for RFID tags. It was originally created by MIT's Auto-ID Center and is currently directed by EPCglobal, an organization dedicated to the global standardization of EPC. The EPCglobal stack is the de facto standard for retail and consumer goods industries.

NFC (Near Field Communication): Is a collection of standards that enable the wireless exchange of data between mobile communication devices in close proximity. NFC is currently being used to exchange personal data and as in electronic payment systems.

RFID (Radio-Frequency Identification): Is the use of an object (typically referred to as an RFID tag) incorporated into a product for the purpose of identification and tracking using short-range wireless communication. RFID tags store information and can be read at short range with an RFID reader.

Ubiquitous Computing: Is a research paradigm that emerged from anthropological studies at Xerox Parc in the late 1980s. Marc Weiser proposed a human-centric vision of a many-to-one relationship between computers and humans.

The Protection Policy for Youth Online in Japan

Nagayuki Saito

Ochanomizu University, Japan

Madoka Aragaki

Business Breakthrough University, Japan

INTRODUCTION

In recent years, Internet use among young people has been associated to various social problems in many different countries. Examples include miscommunication by text, billing fraud, access to illegal content, and contact with ill-intentioned people. Especially in Japan, the use of smartphones has spread very rapidly among teenagers and young adults since 2012, generating tremendous changes in their online environment. These changes have triggered the abovementioned problems.

To tackle these problems, “the Act on the Development of an Environment that Provides Safe and Secure Internet Use for Young People” (Act No. 79 of 2008) was enforced in April 2009 in Japan. Because Article 3 defines the skills needed to use the Internet efficiently, it is important to empower teenagers and young people to develop risk management skills by using Internet effectively.

For this reason, it is crucial to optimize educational policy to meet the needs of young people. Doing so will require criteria on which to review the current policy. It is also important to evaluate the Internet literacy of teenagers and young people, and to reform educational policy and its implementation to reflect the results of this assessment.

This study aims to develop ILAS, the Internet Literacy Assessment Indicator for Students, making it a more effective and visible tool for developing young people’s coping skills, reducing their online risks, and enabling them to use the Internet

more safely. This indicator will be evidence based and designed to optimize educational policy; it can play an important role as a decision-making system for designing effective educational policy.

BACKGROUND

Review of Evidence Based Policy Making

OECD (2012a) advised all stakeholders to reduce online risks and provide a safer Internet environment. This recommendation obliges every stakeholder to provide a safer online environment for teenagers and young people. To provide effective protection, it is important to implement a youth protection policy at every level of government, as well as in the private sector and educational organizations. Without clear role definitions, it will be difficult to implement a concrete protection policy.

The most effective way to solve these problems is to think about each problem separately, clarifying the political tasks each sector should deal with. One tactic that can help to achieve this is to adopt an Evidence Based Policy (EBP).

An EBP is an approach derived from Evidence Based Medicine; it was proposed by Gordon Guyatt at Manchester University in Canada (Tsutani 2000). EBP is used in areas such as social policy, educational policy, and welfare policy (Sowaki 2010). The OECD (2007) has argued

that EBP-based policy making enables people and organizations to choose clear and simple evidence from among many options. EBP has been widely adopted in various policy areas for evidence based policy making.

Nishimura (2005) pointed out that evidence should be based on “objective and politically neutral statistical indicators.” Such evidence would gain public understanding and help to establish trust between government and society (OECD 2004). In addition, the OECD (2012) has emphasized the need to set indicators as metrics of the evidence, allowing people to visualize the actual condition of each political area.

From these discussions, it seems clear that EBM can be effective in supporting rational decision making for effective educational policy implementation. One key measure to promote the policy will involve establishing an indicator to evaluate the evidence.

Review of the Indicators Adopted in Each Educational Policy Area

In reviewing previous studies related to EBP, this section will focus on studies carried out at the level of government. Examples include the “Flash Eurobarometer” implemented for EU member countries and the “Fact-finding Survey on Young People’s Online Usage Environment” carried out by the Japanese Cabinet Office. In addition, this study will clarify the differences between these earlier studies and ILAS, touching on the social and academic impact of this study.

1. Review of the International Situation

The EU has been a pioneer in conducting research on this problem, launching the “Safer Internet Program,” which conducted actual condition surveys on Internet use in member countries. The EU also carried out quantitative research on children in 2003 and 2004. In 2005, the European Commission conducted a face-to-face questionnaire survey of children from member countries (European

Commission 2005); in 2007, the group interview method was used (European Commission 2007). In the following year, the EC conducted an actual condition survey of children’s Internet use and guardian control policies (European Commission 2008).

These studies focused on children’s actual usage of the Internet, geographic features, psychological conditions, parental controls, and educational policies at home. Their results offered insight into the Safer Internet Program and provided basic data to both InSafe, an international organization that advocates information literacy and morals, and INHOPE, an international hotline against harmful content (European Commission 2009).

In the UK, former Prime Minister Tony Blair appointed Dr. Tanya Byron (2008) to study children’s Internet use and address the emerging related social problems. Her results produced detailed policy proposals aimed at clarifying the different roles of the government and private sector. Following Byron’s review, the Office of Communications released “Ofcom’s Response to the Byron Review” in March 2008, highlighting the need to enhance the media literacy of children and their guardians as well as to implement self-regulation by industry groups. This report also identified the regulation of content delivery and user access as crucial methods for the self-regulation of industry groups (Office of Communications 2008).

In the United States, additional surveys were conducted by private and non-political organizations and think tanks. For example, the Family Online Safety Institute (2013), which advocates online safety for children and their families, conducted qualitative and quantitative studies on 558 children between the ages of 13–17, living in the US. Their results showed that the number of children connecting online through mobile phones increased from 43% in 2012 to 64% in 2013. The Pew Research Center (2012) researched the experience of parental control, surveying 802 guardians of children aged 12–17. Their results revealed that women (51% vs. 49% of men) under 40 years old

(54% vs. 48% over 40), who were white (59% vs. 31% African American) and had higher household incomes were the main users of parental control methods. In addition, the Cyberbullying Research Center (2015) reported the results of a survey on the impact of cyberbullying on the lives of 15,000 American children since 2002. The Center's results suggested that the number of children exposed to cyberbullying had increased from 18.8% in 2007 to 36.6% in 2014.

The Organization for Economic Cooperation and Development (OECD) has emphasized the importance of evidence based policymaking. The OECD Council adopted a "Recommendation on the Protection of Children Online" in February 2012, aiming to establish a foundation to promote co-regulation by each stakeholder for efficient policy implementation to address the identified problems (OECD 2012). This recommendation focused on the need for an evidence based policymaking approach for managing complex policy through enhanced policy coordination. For example, it suggested that enhanced Internet literacy among children and their guardians would be a viable solution, to be determined by evaluating actual usage situations.

Saito (2015) reported the results of an Internet Literacy Assessment Indicator for Students (ILAS), developed through a collaborative effort by the OECD Science, Technology and Industry Directorate and the Japanese Ministry of Internal Affairs and Communications; this project targeted adolescents, measuring their capacity to use the Internet safely and securely. This report investigated the differences in the ILAS test score of students who had bad experiences online and those who had not. It found that the percentage of questions answered correctly by students who had bad experiences online was higher than that of those who had no bad experiences (71% vs. 65%). Thus, adolescents can develop online literacy by coping with bad experiences through Internet usage. These reports recommended that the policy to be implemented not be too strict (e.g., an online ban). It recommended that policies worldwide

should support adolescents in developing online literacy through online experiences, while promoting filtering measures, to be implemented through a step-by-step approach.

2. Review of the Japanese Situation

In Japan, the Cabinet Office has conducted an annual "fact-finding survey on young people's online usage environment" to assess the online usage of teenagers and young adults, and their guardians' approach to protection since 2009. The main data gathered reveal hours of online use, geographical locations, and aspects of youth behavior. Guardians were asked about filtering and rules at home.

Article 3 of the "Act on Establishment of Enhanced Environment for Youth's Safe and Secure Internet Use" Appendix defines the role of the government in terms of conducting reviews: three years after implementation, appropriate measures will be summarized and undertaken. Following Article 3, a survey has been conducted to evaluate the improvement of the young people's online environment. Its main purpose was to gather basic data to evaluate the online use and behavior of teenagers and young adults, as well as filtering recognition, filtering usage, and the drawbacks of filtering.

The Importance of the Internet Literacy Assessment Indicator

As mentioned above, every governmental organization is constantly evaluating children's online usage. These results reveal the actual situation, in regard to children's online usage, education, parental education, and views of parental control. By reflecting these results for educational policy making, it will be possible to establish a protection policy for children and their parents. Political costs will be kept to a minimum by appropriately implementing effective policies.

To enhance the effectiveness of EBP, "children's ability to avoid online risks" should be

evaluated, even though this factor was not included in the EU's, "Flash Eurobarometer" or the Japanese Cabinet Office research. In this section, it will be argued that problems can be tackled by evaluating "children's ability to avoid online risks."

1. Adjusting the Strength of Child Protection Measures

By evaluating children's ability to avoid risks, it is possible to adjust the strength of technical measures for child protection, such as filtering. When filtering became obligatory, the Ministry of Internal Affairs and Communications working team focusing on illegal and harmful online content argued that there were three major problems.

The first is the uniformity problem: the question of whether uniform filtering is appropriate, given the wide range of risk competency among children of elementary school to high school age. The second problem involved filtering technology. Under the white list algorithm, many harmless websites are excluded; only official websites can be accessed. On the other hand, a black list algorithm blocks all websites in certain categories, regardless of whether these websites are harmful or not. The last problem involves convenience: whether controlling access to community websites that are essential to children's social life is appropriate or not (Ministry of Internal Affairs and Communications 2008).

By evaluating children's ability to avoid risks, it will be possible to adjust the strength of technical measures for child protection to reflect a child's developmental status and computer literacy level. This adjustment will not only optimize the level of online protection, but will also ensure that children have as much freedom in their online activities as possible.

2. Optimization of the Awareness Educational Policy

By evaluating the children's ability to avoid risk, it will be possible to optimize the content of awareness education. Awareness education has

depended on the discretion of educators and a limited discussion about whether to include or make it a priority to teach children about online risks.

The indicator will make visible every risk avoidance ability that children should acquire; as a result, educational content will be optimized. The optimization of educational content can and should also be customized to reflect children's skills.

Previous research results were not able to offer enough adjustment for child protection. For example, earlier research evaluated the number and type of educational experiences, but failed to assess how much online risk avoidance ability was acquired. It was difficult to assess child protection policies, because it was impossible to evaluate which types of ability were inadequate.

If online risk avoidance ability is evaluated, it will be possible for education to focus on building the abilities that children lack. Moreover, by knowing which ability is insufficient, it will be possible to change the specifications of online services for children, and to review several policies based on current laws, such as the "Act for the Establishment of an Enhanced Environment for Young People's Safe and Secure Internet Use."

3. Policy Making that Reflects Personal and Regional Backgrounds will be Possible Through this Analysis

Although this study has aimed to establish indicators that can evaluate the online risk avoidance ability of children, it will also help to design protection policy that reflects personal and regional backgrounds; it can achieve this by analyzing the relationship between children's test scores and background information. For example, by analyzing the relationship between risk avoidance ability test scores and regional data, it will be possible to show children's average risk avoidance ability in each region. This will make it possible to establish child protection policies that reflect regional differences. Implementing customized awareness education in each region will enhance children's risk avoidance ability and lead to both a regional and national enhancement of skills.

Overview of This Initiative

SOLUTIONS AND RECOMMENDATIONS

The Development and Implementation of ILAS by the Japanese Government

These discussions show that evaluating young people's online literacy and reforming and implementing educational policy that reflects these results will optimize the educational policies of all stakeholders for each childhood developmental phase. It is therefore important to develop Internet literacy indicators based on previous EBP to evaluate children's risk avoidance ability. By using risk avoidance ability as evidence, it will enable to offer appropriate protection to children, while ensuring their online freedom.

In Japan, the Ministry of Internal Affairs and Communications has developed the Internet Literacy Assessment Indicator for Students (ILAS) in 2012 in order to implement the OECD recommendations at governmental level; ILAS aims to measure children's online literacy skills and to evaluate their ability to cope with typical online risks.

ILAS systematically defined "the ability all children should acquire against online risks" (see Table 1). It is the indicator used to evaluate these abilities by means of a test (the National Institute for Information and Communications Policy 2012a). It is similar to the OECD's PISA test, which evaluates the academic skills of 15-year-old students; however, ILAS evaluates online risk coping skills. Like the PISA test, ILAS evaluates children's ability to cope with online risks and

Table 1. Classification table of online risks

Main Category	Significant Category	Sub-Category
I Illegal & Harmful Information Risks	A Illegal Information	1 Copyright, portrait rights, criminal threats, dating sites, etc.
	B Harmful Information	1 Content offensive to public order and morality, adults-only content, etc.
II Inappropriate Usage Risks	A Inappropriate Contact	1 Libel
		2 Anonymous SNS
		3 Non-anonymous SNS
		4 Spam
		5 Applications
	B Improper Transactions	1 Fraud, sale of improper products, etc.
	C Inappropriate Usage	1 Excess Internet consumption
		2 Dependence
III Privacy & Security Risks	A Privacy Risks	1 Leakage of private and/or personal information, inappropriate disclosure
	B Security Risks	1 Impersonation through unauthorized access, etc.
		2 Viruses

Source: National Institute for Information and Communications Policy (2012a)

visually represents its results by area. It also provides “criteria for judgement” for governmental and regional decision-making, online companies’ social responsibility, the activities of child protection organizations, and school decision-making.

In 2012, a pre-test was given to 2,464 10th grade students from 23 high schools to evaluate online literacy in Japan. ILAS was used to evaluate online risk avoidance ability and another questionnaires used to assess awareness of cell phone risks. By analyzing these indicators, researchers tried to evaluate the relationship between risk avoidance ability and cellphone use (see Table 2).

Visualization of Children’s Online Literacy by ILAS

In this section, the data collected from 2,464 students through the ILAS pre-test will be discussed.

1. Literacy in Each Risk Category

When analyzing online literacy as an ILAS risk category, the percentages of questions answered correctly in the sections on “irregular trading risks

Table 2. Overview of the pre-test

Time Required	50 Minutes
Number of questions	49 items (multiple-choice)
Contents	Description of the CBT: 10 minutes Pre-questionnaire: 5 minutes Implementation of the Pre-Test: 35 minutes Post questionnaire: 5 minutes
Investigation period	May 30, 2012 to July 30, 2012
Subjects	2,464 first year high school students
Number of schools	23 Schools

Source: National Institute for Information and Communications Policy (2012b)

(55.09%)” and “security risks (59.48%)” were lower than other categories of risk (see Figure 2).

When asked about “irregular trading risks,” it is likely that 15-year-old students will have had limited experience of online trading. Although it is possible to enhance their literacy through online trading, it is important to teach them the risks of online trading before they engage in it, to enhance their risk competency and avoid actual risk.

Next, “security risks” may be a challenge for students who are not familiar with technical

Figure 2. Average percentages of questions answered correctly in each risk category (n=2,464)
Source: Saito (2015)

subjects because they involve technology. It is important to ensure that students have a chance to learn about security, and teaching them in small steps to avoid learning failure. These things are important for developing the awareness education plan.

When thinking about the policy-making strategy of each stakeholder, governmental and regional organizations with an obligation to provide social education and online companies with social responsibility obligations must review

their educational programs to make sure that they include opportunities to learn about “irregular trading risks” and “security risks.”

Educators and parent-teacher associations should establish systematic teaching bodies and enhance their teaching ability. Parents should learn about these risk areas and should enhance their ability to protect and control their children (see Table 3).

2. Literacy and the Population of Cities

Next are the results about the relationship between children’s online literacy and the population of their cities. These showed that the percentage of questions answered correctly by students from cities with populations of less than 300,000 were low in 3 risk category areas. In addition, the total percentage of questions answered correctly was 74% in cities of than 500,000; 73% in cities of more than 300,000 people; and 59% in cities of less than 300,000 people ($F(2,461) = 192.06$, $p < 0.001$). Thus, as population declined, the percentage of questions answered correctly also declined (see Figure 3).

Table 3. Political challenges of awareness education at each layer

Stakeholder	Political Challenge
Governmental and regional organizations	Enhancement of awareness education relating to “irregular trading risks” and “security risks”
Educators and parent-teacher associations	Establish systematic teaching bodies and enhance their ability to teach students about “irregular trading risks” and “security risks.”
Parents	Learn about “irregular trading risks” and “security risks” and enhance their ability to protect and control their children.

Figure 3. The relationship between the percentage of questions answered correctly by students and the population size of their cities (n=2,464)

Source: Saito (2015)

These results may reflect the fact that larger cities offer more access to communication services, promoting frequent communication between students in daily life enhancing their online literacy.

Results suggest that online literacy differs, depending on the city population, and that smaller cities need to be aware of the potential for lower levels of literacy. The lower literacy rates in small cities may reflect several factors, including the real world communication divide, and a lack of social capital when acquiring online information.

When thinking about the implementation of awareness education, small cities tend to have more limited social educational networks than larger cities. For example, larger cities have organized bodies, which host social education events, such as workshops and symposiums—regularly providing awareness education. Smaller cities have fewer such organizations and face difficulties in providing awareness education. Although online networks reach every city, regardless of offline networks, the same set of online risks exists for all children in all cities, regardless of size. It is therefore important to provide awareness education throughout the country.

To tackle this problem, government should collaborate with local authorities and regional branches to provide nation-wide awareness education. The private sector should communicate with its regional branches and provide awareness education activities as an aspect of corporate social responsibility.

In addition, educational committees and parent-teacher associations need to hold workshops to enhance their teaching ability in a systematic

Table 4. Challenges related to regional differences in online literacy

Stakeholder	Political Challenge
Governmental and regional organizations	- Government should collaborate with local authorities to provide nation-wide awareness education - Private sector should communicate with its regional branches and provide awareness education locally
Educators and parent-teacher associations	Hold local workshops to enhance their teaching ability in a systematic way
Parents	Attend local workshops actively and enhance their protection and control ability

Figure 4. Cross analysis of the percentage of questions answered correctly by students with bad online experiences and students without such experiences (n=2,403)

Source: Saito (2015)

way. Parents should actively attend local workshops and enhance their protection and control ability (see Table 4).

3. Bad Online Experiences and Online Literacy

Next, the percentage of questions answered correctly by students with bad online experiences, and students without such experiences were compared. Results showed that the percentage of questions answered correctly by students with bad online experiences was higher than that of students without such experiences (71% vs 65%, $t(2,235.53) = 8.07, p < 0.001$) (see Figure 4). There was a particularly large difference in three areas of privacy security risks (67% vs 61%). The results suggested that students gained online literacy skills by dealing with bad online experiences.

Results showed that students who had had bad online experiences had higher levels of online literacy than students who had not had such experiences. This suggests that too much regulation of Internet use could have a negative effect on students' ability to learn online literacy. Thus, children's online freedom and protection should be balanced in any child protection initiative (OECD 2012b).

To deal with such problems, government should support appropriate technical regulation and private activities that aim to establish social systems. It should also provide many opportunities for awareness education so that children can gain risk avoidance ability. To promote effective policy

Table 5. Challenges resulting from too much online regulation

Stakeholder	Political Challenge
Governmental and regional organizations	- Government should support appropriate technical regulation and private activities aiming to establish social systems. Also, government should provide wide opportunities for awareness education to children, so that they can acquire risk avoidance ability. In addition, the government should conduct continual research on children's online literacy. - The private sector should work on appropriate self-regulation and promote awareness education so that children themselves can gain risk avoidance ability.
Educators and parent-teacher associations	Communicate with homes and advocate continuously for awareness raising.
Parents	Enhance their own protection and control ability at home, and help their children gain online literacy.

implementation, the government should also continual research on children's online literacy.

The private sector should work on appropriate self-regulation through cooperation with government, and should promote awareness education so that children themselves can gain risk avoidance ability.

In addition, schools and parent-teacher associations should avoid banning online activities for children. Instead, they should communicate with homes and advocate continuously for awareness raising. Parents need to enhance their protection and control ability at home, and help their children can gain online literacy (see Table 5).

FUTURE RESEARCH DIRECTIONS

This study showed the future direction of policymaking for each layer of stakeholders working for youth protection based on ILAS analysis. The government, local authorities, and private companies form the macro-layer; schools and parental organizations constitute the meso-layer; and parents form the micro-layer.

Further research is needed on the problem, including study of "irregular trading risk" and "security risk," which were pointed out by this study. In addition, the problem of reaching out to small cities to provide awareness education has room for further inquiry, such as (1) evaluation of the implementation of child protection policy by each stakeholder and (2) analysis of the cooperation and synergy between each stakeholder.

CONCLUSION

This study developed an appropriate test to evaluate children's ability to use the Internet safely and securely. It discussed the problems involved in promoting awareness education in weaker areas, such as "irregular trading risk" and "security risk." It also discussed regional differences in online literacy and the importance of helping children to

acquire risk avoidance ability through their own efforts. To tackle these problems, this study has proposed political strategies that each stakeholder (including government, local authorities, companies, schools, and parents) should use to promote child safety at each childhood developmental stage. Our proposals can support the decision-making of every stakeholder enhance the effectiveness of this policy.

The next step, following on from this study, is to implement the recommended political strategy for other stakeholders. This study provides basic evidence to support policy making, thus contributing to a safe and secure online environment for children and young people.

ACKNOWLEDGMENT

This study could not have been completed without the cooperation of the members of the Committee on the Internet Literacy Assessment Indicator for Students, Japan and the Ministry of Internal Affairs and Communications, Japan.

This research was partially supported by the Ministry of Education, Science, Sports and Culture, through a Grant-in-Aid for Scientific Research (C), 2014-2016 (26330389, Nagayuki Saito).

KEY TERMS AND DEFINITIONS

Awareness Education: Education designed to enhance knowledge/attitudes that can help to avoid various online risks ensure appropriate Internet use.

Evidence Based Policy: A policy making method based on actual proof. It was first advocated as Evidence Based Medicine by Gordon Guyatt, University of Manchester, Canada in 1991. It has subsequently been used widely in social policy, educational policy, and social welfare policy.

Internet Literacy Assessment Indicator for Students (ILAS): An indicator developed to evaluate online literacy, especially the effectiveness of coping skills/morals in reducing online risks/threats. It was released by the Ministry of Internal Affairs and Communications in September, 2012.

Online Risks: Inclusive term covering various online risks, including cyberbullying, online addiction, cyber grooming, security problems, and the leakage of personal information.

Risk Categories: Classification of online risks defined by ILAS. ILAS classifies 3 major

online risks as Illegal & Harmful Information Risks, Inappropriate Usage Risks, and Privacy & Security Risks. It also defines 7 significant categories and 13 sub-categories. In addition, it defines 186 coping skills, which can be used to protect against online risks.

Security of Identity-Based Encryption Algorithms

Kannan Balasubramanian

Mepco Schlenk Engineering College, India

M. Rajakani

Mepco Schlenk Engineering College, India

INTRODUCTION

The concept of Identity Based Cryptography was proposed in (Shamir, A., 1984) which introduced the idea of using arbitrary strings such as e-mail addresses and IP Addresses to form public keys with the corresponding private keys being created by the Trusted Authority (TA) who is in possession of a system-wide master secret (Srinivasan, S., 2010). Then a party, Alice who wants to send encrypted communication to Bob need only Bob's identifier and the system-wide public parameters. Thus the receiver is able to choose and manipulate the public key of the intended recipient which has a number of advantages. While Identity Based Cryptography (IBC) removes the problem of trust in the public key, it introduces trust in the TA. As the TA uses the system-wide master secret to compute private keys for users in the system, it can effectively recompute a private key for any arbitrary string without having to archive private keys. This greatly simplifies key management as the TA simply needs to protect its master secret.

Some of the earlier Identity Based Cryptosystems proposed such as the one by Cocks (Cocks, C., 2010) and Boneh (Boneh, et.al., 2007) were not based on mathematics of pairings. The Identity based cryptosystem (the term Identity Based Cryptography refers to this set of algorithms whereas the term Identity Based Cryptosystem refers to a specific algorithm) was introduced by Boneh and Franklin (Boneh, et.al., 2001). An Identity Based Encryption or IBE (the term IBE is used to denote

a specific Identity Based Cryptosystem) scheme has the following four algorithms: Setup, KeyDer, Enc and Dec. This chapter discusses the algorithms of the IBE schemes and compares them based on the implementation efficiency. An extension to the basic IBE scheme is the Hierarchical IBE proposed by Horwitz and Lynn (Horwitz, et.al., 2001).

In contrast to the basic standard model of IBE, a Random Oracle Model (Bellare, et.al., 1993) may be used where proofs of security are obtained by replacing hash functions with "Random Oracles" that output truly random values for every distinct output. This chapter discusses IBE schemes based on the Random Oracle Model IBEs and compares them with the standard model IBE.

An extension of the above schemes with multiple Trusted Authorities (TAs) instead of a single TA is also possible. An architecture for the implementation of the IBE is discussed along with the security of the various schemes.

BACKGROUND

The public key encryption is a cryptographic system that uses two keys -- a *public key* known to everyone and a *private* or *secret key* known only to the recipient of the message. When user Alice wants to send a secure message to user Bob, she uses Bob's public key to encrypt the message, Bob then uses his private key to decrypt it. An important element to the public key system is that the public and private keys are related in

such a way that only the public key can be used to encrypt messages and only the corresponding private key can be used to decrypt them. Moreover, it is virtually impossible to deduce the private key if you know the public key. Users will exchange public keys; this transaction does not need to be done in a secure manner because the release of public keys does not threaten the security of any private information. After this swap, someone who wishes to send private information to another user will encrypt the data with the intended recipient's public key and then pass along the encrypted message. The recipient, who will keep his or her private key secure under any circumstance, can use the private key to decrypt the encoded message.

Keys in public-key cryptography, due to their unique nature, are more computationally costly than their counterparts in secret-key cryptography. Asymmetric keys must be many times longer than keys in secret-cryptography in order to boast equivalent security. Keys in asymmetric cryptography are also more vulnerable to brute force attacks than in secret-key cryptography (Halevi, S. et.al., 1987). Public-key cryptography also has vulnerabilities to attacks such as the man in the middle attack. In this situation, a malicious third party intercepts a public key on its way to one of the parties involved. The third party can then instead pass along his or her own public key with a message claiming to be from the original sender. An attacker can use this process at every step of an exchange in order to successfully impersonate each member of the conversation without any other parties having knowledge of this deception. In order to tackle the issues surrounding the generation, distribution and safekeeping of the private and public keys and also simplify the process of obtaining the public keys, the identity based Encryption was invented.

Many different Identity Based Cryptosystems have been proposed. Some of them use the concept of a Random Oracle. A popular methodology for designing cryptographic protocols consists

of the following two steps. One first designs an ideal system in which all parties (including the adversary) have oracle access to a truly random function, and proves the security of this ideal system. Next, one replaces the random oracle by a "good cryptographic hashing function" (such as MD5 or SHA), providing all parties (including the adversary) with a succinct description of this function. Thus, one obtains an implementation of the ideal system in a "real-world" where random oracles do not exist. This methodology was formulated by Bellare and Rogaway (Bellare, M., et.al, 1993) and has been used in many works.

AN IBE SCHEME

An IBE scheme is defined in terms of four algorithms *Setup*, *KeyDer*, *Enc* and *Dec*:

- **Setup:** On input 1^k outputs a master public key mpk which includes system parameters $params$, and a master secret key msk . We assume that $params$ contains descriptions of the message and ciphertext spaces, $MsgSp$ and $CtSp$. This algorithm is randomized.
- **KeyDer:** A Key derivation algorithm that on input mpk and msk and identifier id , returns a private key usk_{id} . This algorithm may or may not be randomized.
- **Enc:** An encryption algorithm that on input mpk , identifier id and a message $m \in MsgSp$, returns a ciphertext $c \in CtSp$ and is written as $c = Enc(mpk, id, m)$. This algorithm is usually randomized and if randomness is emphasised it is written as $c = Enc(mpk, id, m; r)$.
- **Dec:** A decryption algorithm that on input mpk , a private key usk_{id} and a ciphertext $c \in CtSp$ returns either a message $m \in MsgSp$ or a failure symbol $\perp$.

PAIRINGS IN ELLIPTIC CURVE CRYPTOGRAPHY

Pairing based Cryptography which builds on the foundation of Elliptic Curve Cryptography has become an active area of research since the work of Boneh and Franklin (Boneh, D., et al.,). Pairing based cryptography is introduced here to show how Identity based Cryptosystems can be constructed.

Let q be a large prime and m an integer with $m \geq 1$. Let F_{q^m} be a finite field with q^m elements. Here q denotes the characteristic of the field and m the extension degree. $F_{q^m}^*$ denotes the multiplicative group of F_{q^m} . The Elliptic curve E over F_{q^m} is denoted by E / F_{q^m} and is defined to be the set of elements $(x, y) \in F_{q^m} \times F_{q^m}$ satisfying an equation of the form

$$y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_5,$$

where $a_i \in F_{q^m}$ for $i=1,2,3,4,5$.

A point $P = (x, y) \in F_{q^m} \times F_{q^m}$ is said to be on the curve if it satisfies the above equation. $E(F_{q^m})$ represents the set of points on the curve and together with the point at infinity forms an additive Abelian Group.

Suppose that $E(F_{q^m})$ has cyclic subgroups G_1 and G_2 of prime order p . Let G_T be the cyclic subgroup of $F_{q^m}^*$ of prime order p . Then an admissible bilinear pairing is a function e which maps a pair of elliptic curve points in G to an element G_T ,

$$e : G_1 \times G_2 \rightarrow G_T,$$

having the following properties:

- **Bilinearity:** Let $P \in G_1, Q \in G_2$ and $a, b \in Z_p^*$, $e(aP, bQ) = e(P, Q)^{ab}$

- **Non-Degenerate:** $e(P, Q) \neq 1$
- **Efficiently Computable:** There must be an efficient algorithm that computes the map e for any pair of inputs.

A survey of applications of pairings in cryptography can be found in (Okamoto, T., 2006).

The mathematics behind pairing is quite involved and is usually treated as a black-box which can be used in the implementation of the security protocols.

THE BONEH-FRANKLIN SCHEME

The steps of the Boneh-Franklin scheme are as follows:

Setup

On input 1^k the algorithm works as follows:

- Runs a Pairing Generation algorithm to obtain (G, G_T, e, p, g) where $e: G \times G \rightarrow G_T$ is a bilinear map
- Sets $params = (G, G_T, e, p, g, H_1, H_2, l)$.
- Sets $h = g^s$ where s is selected from Z_p^*
- Sets $mpk = (params, h)$ and $msk = s$.

Here, $H_1: \{0,1\}^* \rightarrow G$, $H_2: G_T \rightarrow \{0,1\}^l$ for some $l=l(k)$, $MsgSp = \{0,1\}^l$, $CtSp = G \times \{0,1\}^l$.

KeyDer

On input mpk , msk and $id \in \{0,1\}^*$, sets the private key corresponding to $usk_{id} = H_1(id)^{msk}$

Enc

On input mpk , to encrypt a message $m \in MsgSp$, under the identifier $id \in \{0,1\}^*$,

- Parses mpk as $(params, h)$.

- Sets $T = e(H_1(id), h)^r$ where r is selected from Z_p^* .
- Outputs $c = (u, v) = (g^r, m \oplus H_2(T))$.

Dec

On input mpk , ciphertext c and the private key usk_{id} corresponding to identifier $id \in \{0,1\}^*$,

- Parses c as $(u, v) \in G \times \{0,1\}^1$,
- Sets $T = e(usk_{id}, u)$.
- Outputs $m = v \oplus H_2(T)$.

COCKS SCHEME

The Cocks Scheme (Cocks, C., 2001) of Identity Based Encryption is as follows:

Setup

The Trusted Authority gets the following inputs to generate a private key:

- An RSA modulus $n=pq$, where p, q are two private prime numbers which satisfy $p \equiv q \equiv 3 \pmod{4}$.
- A message space $MsgSp = \{-1, 1\}$ and a ciphertext space $CtSp = Z_n$.
- A secure common hash function $f: \{0,1\}^* \rightarrow Z_n$.

KeyDer

Input: Parameters generated by Setup and an arbitrary ID

Output: The private key r .

- Generate a which satisfies $\left(\frac{a}{p}\right) = 1$ with a deterministic procedure ID.
- Let $r = a^{\frac{n-5-p-q}{8}}$ which satisfies $r^2 = \pm a \pmod{n}$.

Encrypt

Input: Parameters generated by Setup, ID of the sender and message M .

Output: Corresponding ciphertext C .

- Select a random t which satisfies $m = \left(\frac{t}{p}\right)$, where m is an arbitrary bit of M .
- Let $c_1 = t + at^1 \pmod{n}$ and $c_2 = t - at^{-1}$
- Send $s = (c_1, c_2)$ to the recipient.

Decrypt

Input: Ciphertext C and the private key and parameters generated by the Trusted Authority.

Output: Original message M .

- Let $\alpha = c_1 + 2r$ if $r^2 = a$, otherwise $\alpha = c_2 + 2r$.
- Return $m = \left(\frac{\alpha}{n}\right)$.

AUTHENTICATED IBE

Here we discuss the authenticated IBE encryption.

Setup

1. Get a security parameter k and then generate a prime number q and Groups G_1 and G_2 of order q , and an admissible bilinear map $e: G_1 \times G_2 \rightarrow G_2$. Select a random generator $P \in G_1$.
2. Generate a random number $s \in Z_q^*$. Let $P_{pub} = sP$.
3. The Trusted Authority selects a random generator $g \in G_1$ and hash functions $H_1: F_q \times G_2 \rightarrow \{0,1\}^n$, $H_2: \{0,1\}^* \rightarrow G_1$, $H_3: \{0,1\}^* \times \{0,1\}^* \rightarrow F_q$, $H_4: \{0,1\}^n \rightarrow \{0,1\}^n$.
4. Return params $= \langle q, G_1, G_2, g, g^s, e, n, P, P_{pub}, H_1, H_2, H_3, H_4 \rangle$ and master key $= s$.

KeyDer

1. The Trusted Authority extracts the private key of user ID_A : $d_A = H_2(ID_A)^s$

Authenticated Encrypt

User A (ID_A) uses private key d_A and another user's id to encrypt a message $M \in \{0,1\}^*$

1. Select a random number $r \in \{0,1\}^n$
2. Let $c_1 = H_3(r, M)$ and $c_2 = e(d_A, H_2(ID_B))$.
3. Return the ciphertext $C = \langle r \otimes H_1(c_1, c_2), E_{H_4(r)}(M) \rangle$.

Authenticated Decrypt

User B uses A's ID ID_A , his private key d_B and params to decipher the ciphertext $\langle U, V, W \rangle$

1. Let $c_2 = e(H_2(ID_A), d_B)$.
2. Let $r = V \oplus H_1(U, c_2)$
3. Let $M = D_{H_4(r)}(W)$.
4. Compare U and $H_3(r, M)$.
5. If $U \neq H_3(r, M)$, discard the ciphertext, otherwise return the message M .

THE HIERARCHICAL IBE SCHEME

In this scheme, every user has an n -tuple ID in the hierarchy tree. The n -tuple ID is composed by the IDs of the user and his ancestors. All users in the i -th level are denoted by $Level_i$. The root of the hierarchy tree $Level_0$ is the trusted Authority.

The following five algorithms form the Hierarchical IBE scheme (Cheng, P., et al., 2012):

Root Setup

1. Based on the security parameter k , generate a big prime q .

2. Use q to generate two fields G_1 and G_2 which satisfy the bilinear map $e: G_1 \times G_1 \rightarrow G_2$
3. Pick an arbitrary element P_0 in G_1 and a random number S_0 in Z_q (q is non zero) as the master-key. Calculate the system parameter $Q_0 = S_0 P_0$.
4. Generate two hash functions $H_1: \{0,1\} \rightarrow G_1, H_2: G_2 \rightarrow \{0,1\}^n$.

Lower-Level Setup

For each user $E_i \in Level_i$, Specify a random number $s_i \in Z_q$

Extract

1. For each user E_i with $ID = (ID_1, ID_2, \dots, ID_i)$, its parent calculates $P_i = H_1(ID_1, ID_2, \dots, ID_i) \in G_1$, where s_0 is the identity of G_1 .
2. Return the private key $S_i = S_{i-1} P_i = \sum_{j=1}^i s_{i-j} P_j$ of E_i and parameter $Q_i = s_i P_0$

Encrypt

1. For a message M and $ID = \langle ID_1, ID_2, \dots, ID_i \rangle$, calculate
 - a. $P_i = H_1(ID_1, ID_2, \dots, ID_i) \in G_1$
2. For any $r \in Z_n$, return the ciphertext: $C = \langle rP_0, rP_2, \dots, rP_i, M \oplus H_2(g_r) \rangle$, $g = e(Q_0, P_1) \in G_2$

Decrypt

For ciphertext $C = \langle U_0, U_2, \dots, U_i, V \rangle$ and $ID = \langle ID_1, ID_2, \dots, ID_i \rangle$, return the message:

$$M = V \oplus H_2 \left(\frac{e(U_0, S_i)}{\prod_{i=2}^t e(Q_{i-1}, U_i)} \right)$$

THE ARCHITECTURE OF AN IBE SYSTEM

The RFC5408 document (<https://tools.ietf.org/html/rfc5408>) describes an architecture for the Identity Based Encryption system. A brief description is provided below:

Identity-based encryption (IBE) is a public-key encryption technology that allows a public key to be calculated from an identity and a set of public mathematical parameters and that allows for the corresponding private key to be calculated from an identity, a set of public mathematical parameters, and a domain-wide secret value. An IBE public key can be calculated by anyone who has the necessary public parameters; a cryptographic secret is needed to calculate an IBE private key, and the calculation can only be performed by a trusted server that has this secret.

The calculation of both the public and private keys in an IBE system can occur as needed, resulting in just-in-time creation of both public and private keys. The ability to calculate a recipient's public key, in particular, eliminates the need for the sender and receiver to interact with each other, either directly or through a proxy such as a directory server, before sending secure messages. A characteristic of IBE systems that differentiates them from other server-based cryptographic systems is that once a set of public parameters is fetched, encryption is possible with no further communication with a server during the validity period of the public parameters.

The server components required for an IBE system are the following:

- **A Public Parameter Server (PPS):** IBE public parameters include publicly-sharable cryptographic material, known as IBE public parameters, and policy information for an associated PKG. A PPS provides a well-known location for secure distribution of IBE public parameters and policy information that describe the operation of a PKG.
- **A Private-Key Generator (PKG):** The PKG stores and uses cryptographic material, known as a master secret, which is used for generating a user's IBE private key. A PKG accepts an IBE user's private key request, and after successfully authenticating them in some way, returns their IBE private key.

Sending a message that is IBE encrypted: In order to send an encrypted message, an IBE user must perform the following steps:

1. Obtain the recipient's public parameters

The public parameters of the recipient's system are needed to perform IBE operations. Once a user obtains these public parameters, he can perform IBE encryption operations. These public parameters may be available at a PPS that is operated by the user's organization, one that is operated by the sender's organization, or by a different organization entirely.

2. Construct and send an IBE-encrypted message

In addition to the IBE public parameters, all that is needed to construct an IBE-encrypted message is the recipient's identity, the form of which is defined by the public parameters. When this identity is the same as the identity that a message would be addressed to, then no more information is needed from a user to send them an encrypted message than is needed to send them an unencrypted message. This is one of the major benefits of an IBE-based secure messaging system. Examples of identities are individual, group, or role identifiers.

Receiving and Viewing an IBE-Encrypted Message

In order to read an IBE-encrypted message, a recipient of such a message parses it to find the URI (Uniform Resource Identifier) or IRI (In-

ternationalized Resource Identifier) he needs in order to obtain the IBE public parameters that are required to perform IBE calculations as well as to obtain a component of the identity that was used to encrypt the message. Next, the recipient carries out the following steps:

1. Obtain the IBE public parameters

An IBE system's public parameters allow it to uniquely create public and private keys. The recipient of an IBE-encrypted message can decrypt an IBE-encrypted message if he has both the IBE public parameters and the necessary IBE private key. The public parameters also provide the URI or IRI of the PKG where the recipient of an IBE-encrypted message can obtain the IBE private keys.

2. Obtain the IBE private key from the PKG

To decrypt an IBE-encrypted message, in addition to the IBE public parameters, the recipient needs to obtain the private key that corresponds to the public key that the sender used. The IBE private key is obtained after successfully authenticating to a private key generator (PKG), a trusted third party that calculates private keys for users. The recipient then receives the IBE private key over a secure connection.

3. Decrypt the IBE-encrypted Message

The IBE private key decrypts the CEK (Content-Encryption Key). The CEK is then used to decrypt the encrypted message.

It may be useful for a PKG to allow users other than the intended recipient to receive some IBE private keys. Giving a mail-filtering appliance permission to obtain IBE private keys on behalf of users, for example, can allow the appliance to decrypt and scan encrypted messages for viruses or other malicious features.

When requesting a private key, a client has to transmit three parameters:

1. The IBE algorithm for which the key is being requested
2. The identity for which it is requesting a key
3. Authentication credentials for the individual requesting the key

The identity for which a client requests a key may not necessarily be the same as the identity that the authentication credentials validate. This may happen, for example, when a single user has access to multiple aliases.

When following the above protocol, attacks may be possible on the system. The following attacks have been identified:

- Passively monitor information transmitted between users of an IBE system and the PPS and PKG
- Masquerade as a PPS or PKG
- Perform a denial-of-service (DoS) attack on a PPS or PKG
- Easily guess an IBE users authentication credential

Additional Information on the structure of the identity and the format of the request protocols can be obtained from RFC5408 (<https://tools.ietf.org/html/rfc5408>)

SECURITY NOTIONS AMONG IBE SCHEMES

Let $A = (A_1, A_2)$ be an adversary and A_1 and A_2 are both Probabilistic Polynomial time algorithms. At the first stage, given the system parameters, the adversary computes and outputs a challenge template τ . A_1 can output some state information s which can be transferred to A_2 . At the second stage the adversary is issued a challenge ciphertext

y^* generated from τ by a probabilistic function in a manner depending on the goal. We say the adversary successfully breaks the scheme if she achieves her goal (<https://eprint.iacr.org/2005/253.pdf>).

Four security goals are considered: One-wayness, Indistinguishability, Semantic Security and non-Malleability.

- **One-Wayness:** Here one-wayness is defined using a two-stage experiment: A_1 is run on the system parameters $param$ as input. At the end of A_1 's execution the adversary outputs $(s; id)$, such that s is state information (possibly including $param$) which she wants to preserve, and id is the public key which she wants to attack. One plaintext x is randomly selected from the message space M beyond adversary's view. A challenge y is computed by encrypting x with the public key id . A_2 tries to compute what x was.
- **Indistinguishability:** In this scenario A_1 is run on $param$, and outputs $(x_0; x_1; s; id)$, such that x_0 and x_1 are plaintexts with the same length. One of x_0 and x_1 is randomly selected, say x_b , beyond adversary's view. A challenge y^* is computed by encrypting x_b with id . A_2 tries to distinguish whether y^* was the encryption of x_0 or x_1 .
- **Semantic Security:** In this scenario, A_1 is given $param$ and outputs (M', hf, s, id) . Here the distribution of M' is designated by A_1 and (M', hf) is the challenge template τ . A_2 receives an encryption y^* of a random message x^* drawn from M' . The adversary then outputs a value v . The adversary hopes that $v = f(x^*)$. The adversary is successful if this can be done with a probability significantly more than any simulator does. The simulator tries to do as well as the adversary without knowing the challenge ciphertext y^* nor accessing any oracle.

- **Non-Malleability:** In this scenario, A_1 is given $param$, and outputs a triple (M', s, id) . A_2 receives an encryption of y^* of a random message x_1 . The adversary then outputs a description of a relation R and a vector $\vec{y}$ of ciphertexts. It is assumed that $y \notin \vec{y}$. The adversary hopes that $R(x_1, \vec{x})$ holds. We say the adversary is successful if this can be done with a probability significantly more than that which $R(x_0, \vec{x})$ holds. Here x_0 is also a plaintext chosen uniformly from M' independently of x_1 .

The attack models for Public Key Encryption (PKE) are Chosen Plaintext attack (CPA) (Goldwasser, S., et.al., 1984), non-adaptive chosen ciphertext attack (CCA1) (Rackoff, C., et.al., 1991), and adaptive chosen ciphertext attack (CCA2) (Dolev, D., et.al., 1991). Semantic Security is widely accepted as the natural goal of encryption scheme it formalizes an adversary's inability to obtain any information about the plaintext from a given ciphertext. IND-CCA2 is considered to be the "right" standard security notion for PKE.

For a public key encryption, the adversary has access, as anybody to the encryption key. It can encrypt any plaintext of its choice. Hence, the basic attack is called "Chosen Plaintext Attack" or CPA in short. But the adversary may have access to more information and namely some decryptions. This is modeled by an access to the decryption oracle.

An adversary is called non-adaptive chosen-ciphertext adversary (or a lunchtime adversary denoted by CCA1 adversary) if it can access the oracle before the challenge ciphertext is known only. An adversary is called an adaptive chosen-ciphertext adversary (or CCA2 adversary if it can access the oracle whenever it wants, that is before and after the challenge ciphertext is known with the sole restriction not to use it on the challenge itself. Due to the particular mechanism, the adversaries are given more power in IBE than in PKE. Essentially the adversaries have access

to the *key extraction oracle*, which answers the private key of any queried public key (identity). The IND-CCA2 security for PKE can be extended to IND-ID-CCA2 security for IBE.

Among the four IBE schemes presented, the Boneh-Franklin scheme is semantically secure under the random oracle model under the Bilinear Diffie Hellman Assumption.

FUTURE RESEARCH DIRECTIONS

In almost all the existing schemes on IBE with a small number of exceptions, there is a single global TA issuing keys to all users in the system and all ciphertexts are created using the public parameters of the that single global TA. In practice there will be more than TA each issuing private keys to a set of users. In addition, some users may have keys issued by more than one TA. In such scenarios, it is not unreasonable to assume that the different TAs may share some common system parameters. This will necessitate that the system parameters may have to be reused. This and other issues in the multi TA setting have not been explored fully (Srinivasan, S., 2010a).

CONCLUSION

The Identity based encryption scheme has been put forward by the cryptographic Community to solve some the issues in obtaining the private and public keys in the Public key encryption. By using an id such as an e-mail address, the user can easily generate a public key. The receiver can obtain the corresponding private key from a Trusted Authority. We can also assume more than one Trusted Authority for providing private keys for the users. This chapter presented a number of Identity Based Encryption schemes such as the Cocks's Scheme, Boneh-Franklin Scheme, Authenticated IBE and Hierarchical IBE. It also presented an architecture of the IBE scheme describing how the users will interact with the Trusted Authority and perform encryption and decryption.

KEY TERMS AND DEFINITIONS

Adversary: An attacker who may try to guess the secret key or the plaintext from a given ciphertext.

Authentication: refers to verifying the identity of a particular user.

Ciphertext: The term ciphertext refers to the output message from an encryption algorithm.

Hash Algorithm: This produces a fixed size output given a message as input. This output can be used to verify message contents.

Identity Based Cryptography: The algorithms that generate the public key using an id of the user. The private key should be obtained from a Trusted Authority.

Identity: Refers to a string that is used to identify an individual. For example, an e-mail address.

Pairing Based Cryptography: The cryptographic algorithms that use the Mathematics of pairings. The most commonly used pairings include Tate Pairing, Weil Pairing etc.

Plaintext: The term plaintext refers to the input message to an encryption algorithm.

Private Key: The secret key in the public key encryption algorithms. This key is kept secret.

Public Key: The Public key is one of the keys used in public key encryption algorithms. This key is made available publicly.

Random Oracle Model: This model assumes the presence of oracle which returns answers to queries similar to Hash functions. It is suggested that the Oracle be implemented through Hash functions.

Signatures: Signing of a message by one's private key. The hash of a message is encrypted with the private key.

Trusted Authority: The Trusted Authority is a third party trusted to distribute keys. In the Identity Based Encryption Schemes, the Trusted Authority provide secret keys.

Steganography Using Biometrics

INTRODUCTION

Steganography is one of the techniques which is used to provide security to the information. There are many other techniques available to do so. Those are cryptography, steganography and watermarking. Cryptography scrambles the message using some encryption algorithm with some secret key. When the receiver receives the scrambled message (cipher), he/she decrypt the message using the proper key (same or different). Last two methods, steganography and watermarking are very much similar to both the methods come from the set of data hiding techniques, but with a different objective. Watermarking is a technique where the cover image is digitally marked using some data hiding technique. The method has some way to logically extract the mark without destroying or harming the cover image. On the other hand, for steganography, the matter of concern is the hidden message only, not the cover image. Steganography pay attention to the degree of imperceptibility where watermarking concentrates on the number robustness of the method. Application of watermarking are copy control, authentication, device control, proof of ownership, etc. Steganography mainly aims to provide the security to the information.

The word steganography is derived from Greek. The Greek word “stego” means cover and “grafia” means writing. The goal of steganography is to conceal the very existence of any secret information in the cover media file. The cover media is any media which usually doesn’t come under suspicion. Selection of cover media has

being changed with the change of technology. In the ancient time, the cover was different, such as messenger’s body part, some natural picture, usual greeting letter, etc.

BACKGROUND

Steganography is a prehistorical practice. From the ancient times, steganography has been using to provide security to the confidential information. Italian mathematician Jerome Cardan reinvented Chinese ancient secret writing method. In that method two parties share a paper mask with holes and after that fill up the blank spaces. The final message appears as an innocuous text. Many secret writing techniques were invented during World War II, such as null cipher, microdot, invisible ink, etc. In the 5th century, BC Hiatus wanted to send some message to his friend secretly. He shaved one of the trusted slave’s head and tattooed a message on it. The slave was sent after his hair grew back. During World War II, Morse codes were encoded in pictures, like long blades of grass indicate dashes and dots were indicated by short blade.

The word biometrics is also originated from Greek word “Bio” which means life and “metric” means measure. Biometric define the measurement of statistical analysis of people’s physical and behavioral characteristics. This is mainly used for authentication, access control, identification. Nowadays, authentication tool/machine developers start to prefer biometrics characteristics as identification or authentication measure rather than

passwords, smart card, etc. Because biometrics is a property which can defines or identify “who are you.” Various biometric characteristics are being used by different authentication machine such as palm geometry, fingerprints, iris, face, skin, etc.

Physical characteristics are related to the feature of the body, such as palm veins, retina, face recognition, DNA, fingerprint, hand geometry, etc. On the other hand, the behavioral characteristic is related to the behavior of a person. It includes signature, voice, gait, typing speed, handwriting, etc. Biometric gets the preference to be a reliable authentication measure than a password, smart card, etc. because biometric characteristics are virtually impossible to steal. Therefore, biometric starts dominating the field of authentication. We can observe the large application of biometric in regular life, e.g. Bank employees use Thumbprint to login into their system, in many universities, offices use biometric punching machine where the biometric feature of employees is used to keep the attendance.

Now, if we focus on the steganography using biometrics, it can be done in two ways, one hides your biometric information in some cover file, and another is the reserve one, i.e., biometric information will carry some secret information. Here a brief discussion related to these two mentioned types are presented.

LITERATURE SURVEY

Anil K. Jain et al. (2003) proposes another method to hide biometric information using steganography. They discuss two scenarios. In the first one, the authors embed the fingerprint information (minutiae) into another fingerprint image, so that attackers do not suspect that the visible fingerprint image is not the actual one. The stego fingerprint image is again encrypted using a secret key to increase the security level. In the second scenario, the minutiae and facial information (Eigen—face coefficient) are hidden in the fingerprint image. Again this stego image embedded in the smart card for authentication.

Hussain Ud-Din et al. (2006) proposes a system for providing better security to the online shopping customers. In this system, there are three main phases. The first phase extract the feature of the biometric information (fingerprint). In the 2nd phase the sensitive information of the electronic shopping card is encrypted and in the final phase extraction biometric feature and encrypted information are embedded in cover image (the image of the shopping card).

The author Yinghuua Lu et al. (2008) proposes a method to improve the security of biometric authentication using lossless and content-based hidden watermarking algorithm. Chaos is employed by the method to encrypt the watermark and the initial condition for chaos are generated by the biometric image of the user. Watermark includes like ID, Palmprint no. etc. which are embedded in the palm print image. Again, the stego palm print image is embedded in the cover image to provide the security to the biometric information as well as authenticate by watermarking the palm print image.

A paper by Abbas Chaddad and Joan Condell (2008), discusses the efficiency of embedding information in the skin tone color space. Anjali A. Shejul and Prof. U.L Kulkarni (2010) proposed a method where secret information is embedded by finding the location to embed using the biometric concept. A DWT based steganography algorithm is used for embedding the information in the skin tone of the human body.

A combination of cryptography, biometric and steganography approach is made by authors Hisham Al-Assam et al. (2013). In the method, the biometric feature is used for remote authentication. On the other, to protect biometric feature of individual, steganography is used. To embed the biometric feature vector, Random LSB scheme is used. Another similar approach is made by Indradip Banarjee et al. (2014) where they integrate the face extraction geometry into the cover image using DWT. Another method combines this three concept again which is suggested by Ashsa Ali, Liyamol (2010). This method uses RC5 encryption

algorithm to encrypt the user's data and embeds the encrypted information into the fingerprint image using some LSB based steganography algorithm.

The author Shivendra Katiyar along with the co-authors (2011) suggests an online voting system where steganography and cryptography have been used to provide added security. The biometric feature, thumb impression is used for authentication. The proposed system also uses the system generated a secret key and SSN no. to log into the voter's account. The system concentrates on the authentication of the voter's identity, but not the confidentiality of the voter's biometric features.

For secure transmission of medical information, a method is proposed by S. Barkathunisha et al. (2013) In this method, they provide a technique to enforce security to the medical information where patient need to send their report to the expert in remote station.

The method proposed by Rasher D. Rashid (2013) hides the feature of a face biometric into a cover image. The authors calculated the PSNR value for the invisibility of the system and recognition rate is calculated using Euclidian Distance. To extract the feature of the face, the method divides the face into multiple frequency bands and each band is divided into non-overlapping blocks. From the blocks, local binary pattern histogram is extracted.

Włodzimerz Kasprzak et al. (2015) suggests a method which uses a printed steganography to authenticate the photo in identity card. This method proposes a steganography technique for authentication of a printed face image.

A. Kapezynski (2011) proposed a hybrid method using biometric and steganography. This approach considers physical and behavioral biometric characteristics. The physical characteristics, the fingerprint is used to hide the behavioral biometric keystroke. Embedding is done by LSB substitution.

D. Goyal proposed Steganography authentication concept using face and voice recognition for secure banking system through mobile. The author uses multiple biometric features for identification.

In the proposed system, the face is used to login into the banking server. After successful logged in, the voice of the user is used to provide better security to the transmission phase. The voice is transmitted using steganography algorithm.

P. Kamble proposed a method for ATM security using multimodal biometrics system with steganography technique. The system embeds the code in the image of the palm print of the user and image is sent to the authentication server with an iris image of the same user.

Many researchers work on steganography using DWT and biometric feature. Sarthi k, in 2013, proposed a biometric based steganography method using circular folding in DWT domain. The method hides the secret message in the skin tone region. To detect skin and non-skin, HSV color space is used. The cover image is cropped after detection of skin tone. DWT is performed on the cropped image. The third plane of the cropped cover images is rotated by 180° using circular folding technique. Next DWT is performed on the folded image and the high-frequency sub-band is used to hide the secret information. Anjali A Shejwal, S. Barve, N. Lavanya (2012) also proposed similar methods where skin tone and DWT have been used.

It has been observed that researchers are constantly searching for a solution for secure online voting system. But, very less work have done in this field. An online voting concept has proposed by N. Gandhi (2014), where the concept of steganography, cryptography using biometrics are used. Similarly, G.M. Kamau (2013) proposed a hybrid steganography method using biometrics (fingerprints) for casting a vote remotely. Using enhanced least significant bit steganography method, the fingerprint template with the voter details are embedded in the voter face image with a Stego key. S. Lokhande (2012) also presented a method using biometrics, cryptography, and steganography with the conjunction of GSM module. The method uses cryptography algorithm (MD5) to generate a unique key using users ID card, users key and time factor. The unique key is embedded in the thumbprint image and send to the authen-

Figure 1. Basic block diagram of steganography

tication server. Few more similar approaches are proposed by N. Malwade (2013), V. J Lakshmi (2014), S Bhattacharyya (2014), Shanthini (2012). S.A.Tambe (2014) approached a method where the fingerprint is used as a cover image to embed the ID of the voter. Embedding process is done in the transform domain using DWT.

STEGANOGRAPHY

A basic steganography system is mainly composed of embedding process and extracting process. Figure.1 illustrates basic block diagram of a steganography system.

The sender selects an unsuspected cover image to embed the secret message. Sometimes, some “key” is used in the embedding procedure, which is optional. The embedding process produces the stego-image and then it is transmitted over the network. The receiver has to run the extracting algorithm with the proper key (if any) to get the message back accurately.

Steganography is a very broad area of application. With the digital revolution, not only mankind gets benefited, but also terrorists and criminals take the advantage to fulfill their suspicious act.

Here, we are focusing only on the positive side of the development. Steganography has many useful applications such as copyright control, smart ID where details of the individual are embedded in the photos, synchronization of video audio secret information circulation etc. While designing steganography method to use in the different field, we always have to consider the main three properties of it. These are-

1. **Imperceptibility:** It is the first property one needs to keep in mind. The basic motive of steganography is to conceal the existing of any message. Higher perceptibility indicates better steganography method.
2. **Capacity:** With good imperceptibility of the stego file, the designer must look after the capacity of the method also. Application of steganography is not limited. So, as per the requirement steganography method should be capable of providing good embedding capacity.
3. **Robustness:** This is also an important property. It is the capacity of the method to withstand the message after some attack or some manipulation operation, such as cropping, rotating, etc.

Some other properties, such as security of the key used in the method, various cost such as computational cost, time cost, are also required to consider.

With the development of steganography, the counter measures of it have also developed in parallel, i.e., steganalysis. Steganalysis is the art of detecting hidden message in the cover file without having any knowledge of the steganography method. There are various steganalysis methods, such as histogram analysis, statistical analysis, etc.

Steganography algorithm can be implemented in various domains. Mainly there are two domains, but further, these are subdivided into many domains. Different researchers visualize the type of steganography methods in various categories. Some of them have divided into six categories depending on the hiding technologies: Statistical method, Distortion techniques, Substitution, Cover generation techniques, Spread spectrum techniques and Transform domain techniques. On the other hand, some researchers have divided depending on the domain, where most of bits are hidden. Those are mainly spatial domain steganography, transform domain steganography, Spread spectrum steganography and model based steganography. To discuss the type steganography methods briefly, we consider the second type division case.

Spatial Domain Steganography

In Spatial domain steganography method, the embedding process is done by directly manipulating the pixel values of the cover image. These type of methods are less complex and less robust. Various approaches in spatial domain are discussed below:

1. **LSB Substitution:** This is the simplest spatial domain technique where the message is embedded in the least significant bit (rightmost). This method can provide good embedding capacity but vulnerable to even minor manipulation, such as rotation, scal-

ing, cropping and addition of noise, lossy compression, etc. Also, it is not robust against stego attacks.

2. **Gray Level Modification:** This technique doesn't embed or hide the data. It uses a mathematical function to map data by modifying their gray level. To map data within the cover image, this technique uses some odd even mapping. For example, odd values map 1 and even maps 0. This method can provide high embedding capacity with low complexity.
3. **Pixel Value Differencing:** This method uses the difference between adjacent pixels. A larger difference indicates the presence of an edge, and according to human visual properties, the human eyes can tolerate more changes in edge areas than that of flat areas. This property leads to high embedding capacity without noticeable perceptibility. Some methods have been developed using this concept and gain good results. These methods are also vulnerable to steganalysis method and stego attacks.
4. **Quantization Index Modulation (QIM):** Brain Chen (2001), proposed QIM algorithm which has higher embedding capacity. It also allows to control robustness and distortion. To embed the information in the cover file using QIM, it first modulates an index or sequence of indices with the embedded information and then quantized the host signal with associated quantizer or sequence of the quantizer. There are some other techniques come under this category, such as vector quantization, singular value decomposition, side-match vector quantization, search order code (SOC).
5. **Multiple Base Notational System (MBNS):** In this method, secret information is converted into symbols (e.g. integer numbers). The pixels of a cover image are modified in such a way that the remainders are equal to symbols after dividing the pixel values by the bases. The degree of the local variation

of pixel values in a cover image determines the specific bases. This method achieves high payload capacity and performs better in terms of PSNR quality factor and Watson's metric.

6. **Prediction Based Steganography:** Direct manipulation or alteration of pixel value leads to the significant distortion. Predictive-based steganography is suggested to overcome this issue where pixel values are predicted using predictor. Here, prediction error values are modified to embed data instead of modifying the pixel values. The gradient adjusted prediction and median edge are mainly used in prediction based image coding.

Transform Domain

All digital images are composed of low and high-frequency component. Low frequency is represented by flat and plain areas whereas sharp transition and edges contribute in high-frequency component. Changes in the low frequency are easily visible to the human visual system. Therefore, embedding an equal number of information in both frequencies is not feasible. It embeds the message bits in optimally chosen coefficients. Coefficients are calculated from the cover image using some transformation function. There are a number of transformation functions available, such as DCT, DWT, Integer transform, Haar transform, Hadamard transform, contourlet transform, ridgelet transform, ripplelet transform, DD DT DWT etc. These methods are computationally complex than spatial domain and robust against attacks and image manipulation operations. Some popular transform functions are:

1. **Discrete Cosine Transformation:** In 1974, researcher community working on an image compression has suggested DCT, which turns like a great achievement in this field. The DCT can be considered as a discrete time version of the Fourier cosine series. The com-

putational complexity of DCT is $O(n \log n)$, like FFT, DFT. DCT is a real-valued with fewer coefficient and better approximation of a signal. The 2D DCT compression $c(u,v)$ of a $N \times N$ image signal $f(x,y)$ can be defined as:

$$c(u, v) = \alpha(u) \alpha(v) \sum_{x=0}^{N-1} \sum_{y=0}^{N-1} f(x, y) \cos \left[\frac{(2x+1)u\pi}{2N} \right] \times \cos \left[\frac{(2y+1)v\pi}{2N} \right]$$

where,

$$\alpha(u) = \begin{cases} \frac{\sqrt{1}}{N}, & \text{for } u = 0; \\ \frac{\sqrt{2}}{N}, & \text{for } u = 1, 2 \dots N-1 \end{cases}$$

In 2016, Fengyong Li uses DCT to steganalyze over large scale social network with high order joint features and clustering ensembles.

2. **Discrete Wavelet Transformation:** The word wavelet has been used for decades in digital signal processing and exploration geophysics. First wavelet transformation is Haar wavelet proposed by Alfred haarin 1909. This is a multiresolution transform method. The wavelet transform for a square integration function $f(t)$ is defined by-

$$w_f(a, b) = \int_{-\infty}^{\infty} f(t) \varphi_{a,b}^*(t) dt$$

where $*$ denotes complex conjugate, $\varphi_{a,b}^*(t) = \frac{1}{a} \varphi \left(\frac{t-b}{a} \right)$, a basis (mother) wavelet $\varphi(t)$ by dilations and transition. Here, a and b are scale factor and transition factor respectively. $\frac{1}{a}$ is the normalization factor for energy normal-

ization. For different application different basis function are available. A basis can be modified according to the requirement. Some popular basis are – Haar Basis, Gaussian wavelets, Gabor wavelets, Daurbechies basis.

3. **Walsh Transformation:** In 1923, Walsh defined transform, but in 1823 Hadmard had also achieved a similar result by the application of certain orthogonal matrices which called Hadamard matrices. Hadmard matrices contain only ± 1 . It is equivalent to multidimensional DFT of size $2 \times 2 \times 2 \dots 2 \times 2$ and can be considered as being built out of size two discrete transformation.
4. **Curvelet Transform:** This technique was proposed by Candes and Donoho in 1999. It can be viewed as an extension of wavelet transformation and it became more popular in the same field. This transformation is multi-scale directional transform technique which is an almost optimal non adaptive sparse representation of object with edge.
5. **Contourlet Transformation:** It is also a multiresolution directional tight frame which design to efficiently approximate image. This transformation was proposed by Do and Vetterli in 2002. They construct a discrete domain multiresolution and multidirectional expansion. Non separable filter banks are used to do so in the same manner as wavelet filter bank. This technique represents at 2D image with smooth corners. Contourlet has the properties of multiresolution, localization, directionality, critical Sampling and anisotropy. Method proposed a filter Bank structure to obtain sparse expansion of 2D image having a smooth contour. To implement this double filter bank, the Laplacian pyramid is used for capturing point of discontinuities and to link point of discontinuities into linear structure, a direction filter bank is used.

Spread Spectrum

A well-known concept in digital communication, spread spectrum was proposed by Harvel et al. (1999). The method involves in spreading the bandwidth of a narrowband signal across a wide band of frequencies like white noise. At the decoder side, during extraction process image restoration and error control techniques can be used. It is difficult to detect because the energy of the narrow band signal is low in any frequency band after spreading. The resulting signal is embedded in the cover image to get the stego image. Due to the difference in power of signals (embedded and cover image), the SNR of stego image is very low which result in low detectability. This method provides good embedding capacity and also maintain the robustness against statistical attacks. Statistical properties are preserved because the secret message is spread throughout the cover image.

Model Based Steganography

In 2003, P Shallee proposed a spatial domain technique called Model-based steganography which based on the statistical properties of a cover medium. In this method, the cover image is divided into two parts, and one part is selected for embedding message without altering the statistical properties. A popular adaptive method is proposed by Hoki which it is known as “A block Complexity based Data Embedding (ABCDE). Here noisy block is replaced by the block obtained by embedding the message.

BIOMETRICS

We all are aware of unauthorized access to information. There are a number of methods to prevent unauthorized access. The most common way is to use username and password combination. However, mainly there are three ways to authenticate a user-

1. Something you know. For example, password.
2. Something you have. For example, token.
3. Something you are. For example, measurable physical features.

These three pillars of authentication can be used separately or combinedly for stronger authentication. In some situations, only one way is not sufficient to provide stronger authentication. For example, it would be better if some biometric information is required while withdrawing money using ATM card because ATM card can be stolen, pin code can be guessed.

Biometric assures individual's unique physical and behavioral characteristics to authenticate or recognize their identity. Physical biometric features include fingerprints, facial, Iris, hand palm geometry, retina, etc. Behavioral characteristics are handwriting, signature, voice, keystroke pattern, gait, etc.

The biometric system works by scanning the fingerprint or iris to get the pattern of it, capturing a digital color/grayscale image for face recognition, etc. The feature of the image is transformed into the template using mathematical functions. These biometric templates are added to the database for further identification. A biometric system works for two different purposes; one for adding the template to the database for further reference and another is to find a match with the existing template.

Biometric has occupied the field of authentication because of its special characteristics. Among all characteristics, biometric feature has chosen for authentication based on the following characteristic.

1. **Uniqueness:** It is the most desirable and primary characteristic so that chances of occurring same characteristic of two people is minimum.
2. **Stability:** Chosen feature should not change over time.

3. **Ease of Capturing:** Capturing of the biometric template should be convenient to the user with preventing misrepresentation of the feature.

Because of the special characteristic of biometric, it occupies the place of most secure and convenient authentication tool. This section discusses some of the popular biometric features.

Physical and Behavioral Characteristics

Physical biometric comprises some of the shape or composition of the body like a fingerprint, hand geometry, face, ear, retina, etc. Most of the physical biometrics are time invariant and also satisfy the character of the uniqueness with stability.

1. **Fingerprint:** It is the unique physical characteristic which features can be recorded as arches, loop, whorl pattern with the ridges, minutiae, and furrows. Matching Fingerprint can be done in three ways:
 - a. Minutiae based,
 - b. Correlation based,
 - c. Ridge features.
2. **Hand Geometry:** An optical camera is used by hand geometry based system to capture two orthogonal two-dimensional image of palm and sides of hand. A number of dimensional measures are collected including height, length, width, distance between joints, etc. The system does not consider the fingerprint or Palm print.
3. **Palm Print:** Palm print system takes the image of palm. It is different from hand geometry.
4. **Face:** A quality digital camera is required to capture the facial images of the user. Characteristic of face are analyzed. Many software applications have developed which have facial image authentication, due to the ease of capturing the facial image.

5. **Facial Thermography:** It is similar to the face recognition, except an infrared camera, which is used to capture the image. It detects heat patterns emitted from the skin and created by the branching of blood vessels. Thermograms patterns are highly distinctive.
6. **Vein Recognition:** The vein pattern structure of a user is image processed and stored. It is believed by many researchers that vein biometric recognition can produce high accuracy rate than fingerprint recognition.
7. **Blood Pulse:** It is not as strong authentication measure as it has a high false matching rate. It can be measured on a finger with an infrared sensor.
8. **Retina:** This biometric analyses the layer of blood vessel situated in the back of the eye. The network of a blood vessel in the retina is not genetically determined, and therefore even identical twin do not share the same pattern. Some retina based biometric system used a low-intensity light source through an optical coupler to scan the unique pattern of retina. This kind of system has low false, positive, high reliability, high cost. It is not user convenient because it requires close contact with the reading device.
9. **Iris:** This type of biometric system analyses features of the colored ring of tissue that surrounds the pupil. Iris recognition systems apply mathematical pattern recognition technique to the images of irises of an individual's eye. There are many advantages of iris matching, besides its speed of matching, they are extreme resistant to false matches, stability, and extremely visible organ of the eyes. It also works with contact lenses, eye glasses and non-mirror sunglasses.

Apart from these, there are many more features, such as tongue print, dental scan, ear, nail bed, etc. Here, only the popular ones have been discussed. Biometrics, such as, DNA matching, ear, odor are also used but because of many issues, these characteristics are not so popular than

others. Now, let us give a brief overview of some behavioral characteristic.

1. **Signature:** Signature has been widely used for authentication, and it is also a very old practice. Signature authentication may be either static or dynamic. Static authentication uses only the geometric feature whereas dynamic includes some more features such as velocity, acceleration, pressure, the trajectory of the signature, etc.
2. **Voice:** It is a combination of physical in behavioral characteristics. Physical characteristics, vocal tracts, mouth, nasal cavities, and lips are included and under behavioral, emotional and physical state are considered. Traditionally voice-based authentication divided into text dependent and text independent categories. Text independent authentication is more complex than text dependent because in text dependent, the speaker speaks a predetermined phrase and in text independent, no constraint exists. Regardless of their classification, voice based authentication faces a lot of challenges because of the variability like emotional state of the speaker, misspoken phrases, environmental noise, etc.
3. **Keystroke:** This kind of authentication systems aim to capture the latency period between keystroke and hold time of the user's keyboard interaction to provide a unique representation of each user. The main advantage of this technique is that it allows continuous authenticate since the user can be analyzed over a large period.
4. **Gait:** This type of system authenticate people by the way they walk. To create gait signature, some models are built, based on the temporal and spatial matrices of the human motion. However, gait is not supposed to be very distinctive across individuals. Therefore, it is not suitable for high security scenario. It also involves video sequence analysis, which may be comparatively expensive.

Behavioral characteristic is less stable than physiological. As time passes, changes come in handwriting, voice and gait. These characteristics are also influenced by one's emotional state, physical state, environment, etc. Therefore, the most common biometrics used for authentication is Fingerprint and Iris. These biometric features satisfy the main required properties for authentication. The properties make them popular are:

1. **Stability:** Both the characteristics remain constant in an entire lifetime.
2. **Uniqueness:** Finding two identical fingerprint or Iris is nearly impossible.
3. **Flexibility:** Fingerprint or iris recognition system can be integrated easily into the existing system. It can also be operated as standalone.

Other biometrics are also used, but all biometric features are not equally efficient, secure and user-friendly. For example, facial recognition system fails in case of identical twins and for many other factors like the beard, facial hairs, glasses, scars, etc. Voice, signature, gait also have many issues, like voice, signature is prone to forgers and are affected by environment, time variant, etc. On the other hand, some biometric analysis is costly to use for public authentication, such as DNA matching.

Fingerprint is the most common user-friendly and distinctive biometric. Same is applicable for iris biometric. In spite of all points, people prefer to use fingerprint by fingerprint scanner than placing an eye in IR scanner camera.

STEGANOGRAPHY USING BIOMETRICS

When this biometric information is used to provide security, authentication, then simultaneously they also need security, since biometrics represent a person physiologically and behaviorally. This information is itself very confidential to a person. For providing security, steganography can employ

in this situation. While transferring biometric information over network we have to take care of its confidentiality. Here we have two type of use of biometrics in steganography. In one type, we can use steganography to provide security to the biometric information. In a different kind, we can use biometric information to provide security to secret information.

Security to Biometrics

To prevent the misuse or leaking of any biometric information of a person, one can take advantage of steganography method. We have already discussed that how steganography works and how does it efficient in providing security. Figure 2 shows that the biometric information, the fingerprint is embedded in the cover image 'baboon'. For embedding, any steganography method can be used as the requirement. There are various techniques with different methods in different domains which are already discussed in the former section.

Security by Biometrics

Biometrics image could be a very good/unsuspicious cover image. When a sender sends a biometric image over the network, then generally it is not suspected by the intruder, as because the confidential data biometrics is sent as it is. In that case, we can use the biometric image to hide some secret information. There are some other cases also, where biometric require to hold some information secretly. For example, in some medical report, where the patient's personal information (e.g. name, age, sex etc.) should be kept hidden to others except the receiver, the information is embedded in the medical image secretly. Figure 3 shows the use of biometric information as cover image in steganography. Figure 3(a) shows hiding of secret information in iris biometrics and Figure 3(b), the information of the patient is concealed in the MRI report.

Biometrics characteristics of an individual are very confidential since it defines the person physi-

Figure 2. Security to biometric data

Figure 3. Biometrics image as cover image

cally and behaviorally. Security of these always should be a matter of concern for researchers. We know that many encryption algorithms being used to assist the security enhancement of biometric system, but there are still some issues to resolve. In 2001, Ratha addressed eight primary sources of attacks in biometrics system.

1. Fake biometric at the sensor;
2. Resubmission of old digitally stored biometrics signal (typical replay attack in voice recognition);
3. Override feature extraction;
4. Tampering with the feature representation in network environment;
5. Override matcher;
6. Tampering with stored templates in database;
7. Channel attack between stored templates and the matcher during biometric data or feature template transmission;
8. Decision level override.

We know that the cryptography algorithm scrambles the message, which attracts the intruder to decode the message. To avoid this situation, steganography is used. For example, a person needs to send his fingerprint for some normal online authentication. If that person's activities are being tracked by some intruder without his knowledge, then his fingerprint will also be leaked. That fingerprint may be misused (e.g. online fund transfer, personal account access, etc.) by the intruder further.

SOLUTIONS AND RECOMMENDATIONS

From the literature survey, it is found that biometrics has extensively been used by the developer to provide security and authenticity. Many researchers and developers use a biometric feature such as skin, iris, etc. to hide the secret information. But, the security of biometric information is not much been focused. D. Goyal proposed a steganography authentication system. In that method, the face and voice of the user are embedded in the cover

image and is sent to the bank server. Bank server contacts authentication server to verify and then the transaction takes place.

Here, will present a hypothetical secure voting system for casting a vote remotely. As a responsible citizen, we all wanted to establish the voting right. But due to our busy scheduled life, we may not able to cast our vote each time. It would be beneficial if we could cast our vote through a secure trusty online system. The basic working of an example system is prototype below:

1. Login to the user account through user name and password. The username could be any unique ID, such as SSN no, Adhar no, Voter ID, etc.
2. The system will ask to provide the thump print through some fingerprint scanner which will be integrated part of the system.
3. Without user's knowledge, the system will select a cover image randomly from its database and embeds this information onto the selected cover image using some robust steganography algorithm.
4. The stego image is sent to the authentication server.
 - a. If biometric verification fails, then an error message will be sent to the user.
 - b. If user has already cast a vote, then also an error message will be sent.
 - c. First, the server will check whether the user has already cast a vote or not. If not, then it will send the extracted data to the authentication server database. After verification, a verification number will be generated. The confirmation number will be sent to the user as well as to the voting server as shown in Figure 4 (via sms or email).
5. If the verification number match between the user and voting server, then a secure channel will be established between the two parties otherwise communication link will be disconnected with a message. The connection will be for a limited period only.

Figure 4. Block diagram of secure e-voting system

6. Now the user can cast their vote before the session expires.

Here multimodal biometric authentication can also be applied. With fingerprint, we can use iris also for stronger authentication. For scanning fingerprint, any standard fingerprint scanner can be used. Many technologies have been used including optical, capacitive, RF, thermal, piezoresistive, ultrasonic, piezoelectric.

Biometric Steganography

Fingerprint as the biometric feature is a very good choice for authentication. It holds the important properties of good biometrics: stability, uniqueness, user-friendly, etc. In steganography, the primary goal is to achieve high imperceptibility and it happens when the size the image or message to be embedded is as small as possible. In case of a fingerprint, we can represent it as a binary image without losing any important information. Converting a grayscale image to binary image saves eight times bit. Therefore using this concept we can achieve a very high-quality stego image.

Now, for steganography method, considering the robustness property of transform domain, any

one of the feasible methods can be adopted among transform domain methods. Again for the secret biometric image, we can compress the secret image to reduce the size, so that we can achieve better quality stego image. Figure 5 shows the block diagram with a compression method. Compression can be lossless or lossy. Both the methods are useable here. With lossy compression (e.g. DCT, DWT compression) fingerprint can successfully authenticate a user.

FUTURE RESEARCH DIRECTIONS

Information security has been increased here by the amalgamation of steganography and biometrics to a next level. But being a new area very less joint literature and research is available in this mixed area. The necessity of protection of intellectual property rights is increasing day by day due to most of the information and data being stored in cloud space and being readily available on the internet. Thus the inclusion of both physical and behavioral biometrics in all possible permutations and combinations with transform domain variants of steganography both on software and realization on hardware is to be addressed in future. Then based

Figure 5. Transform domain steganography using compression method

on computational complexity as well as response time and robustness best possible techniques need to be analyzed and optimized to obtain the best possible ways of enhancing security. Thereby, the future research in this area must target these areas.

CONCLUSION

In this chapter presents an introduction to the concept of steganography with a scope. It also discussed the basics of biometrics and different type of it. Steganography with the idea of biometrics such as biometric image as a cover image, biometric image as secret image have been presented. Application of these entire concepts is shown in an online voting system which is now on demand.

KEY TERMS AND DEFINITIONS

Biometrics: It refers to the technology to measure physical and behavioral characteristics of an individual, such as fingerprint, palm print, iris, DNA, retina, signature, keystroke etc. Biometric characteristics are extensively used in authentication and verification process as most of the characteristics are unique.

Cover Media: In steganography, a carrier media is selected to hide the message or to carry the message in it, that carrier media is called cover media. A cover media can be any unsuspecting file, such as natural picture, family photo, video, audio clip, etc.

Cryptography: Cryptography is a technique to secure a communication. It converts the message into some meaningful text (cipher) using encryption algorithm, so that no one can read that message without knowing the decryption algorithm. Depending on the secret key used in the algorithm it is divided into two categories: symmetric - if one key is used for encryption as well as decryption and asymmetric - if two different keys are used for encryption and decryption.

Steganography: It is a technique to provide security to the secret information using data hiding technique. In steganography, a cover media is selected to hide the information. Depending on the place of data hiding it is mainly divided into two categories: Spatial domain - if information is embedded directly in the pixel values and Transform domain - if information is embedded in the coefficient values which are calculated from the pixel values of the cover image.

Stego Image: Stego image is the output of the embedding process. Stego image contains the hidden message either in pixel values or in optimally selected coefficients.

Watermarking: It is a data hiding technique whose primary motive is to authenticate. Watermarking can be visible or invisible. Here the cover image is also important along with the embedded message. Robustness is the main criteria for selection of embedding algorithm.

INTRODUCTION

Recent decades have been characterized by the growth of information technologies in the private and public sectors. The positive impact that ICT has on job performance, as well as the expansion and creation of business opportunities for companies, count as the main drivers for this growth. This growth led to the proliferation of distributed applications and physical devices, and the diffusion of technologies that facilitate social participation and social interaction. All these applications, devices and interactions may contain important information, or give access to sensitive data, putting them at risk.

The rapid diffusion of technology has led to the reduction of active security monitoring, as well as the lack of technically competent people in control of applications and devices. Moreover, the increment in social interaction increases the damage other people can directly or indirectly cause.

Traditionally, security is only considered as strong as its weakest link, and people were considered as the weak links (Schneier, 2003). This thinking triggers a vicious circle. (Adam & Sasse, 1999) stated that users are informed as little as possible on security mechanisms took by IT departments, precisely because they are seen as inherently untrustworthy. Their work has shown that users were not sufficiently aware of security issues and tend to build their own (often inaccurate) models of possible security threats.

Users have a low perception of threats because they lack the necessary information to understand their importance. According to (Sasse & al., 2001) blaming users for a security breach is like blaming human error rather than bad design. Security has, therefore, a human dimension that must be neither ignored nor neglected. The increase in the number of breaches may be attributed to designers who fail to sufficiently consider the human factor in their design techniques. Thus, to undo the Gordian knot of security, we must provide a human dimension to security.

BACKGROUND

Human-Computer Interaction (HCI) is a field concerned with the interaction between people and technology, and how this supports humans in completing tasks to achieve one of more specific goals. Traditionally, it has been involved in analyzing and improving usability.

HCI has been an active area of research since the 1980s. It has focused on improving the design of user interfaces, and helping users transforming their goals into productive actions for the computers. Improving user interfaces and usability is important because poorly designed interfaces increase the potential for human error. In particular, human behavior is largely goal-driven, therefore the execution of activities which help the users to achieve their goals is the main key to create a

usable system. So, when a user “engages with a complex system of rules that change as the problem changes” (e.g. an interface does not present information clearly and coherently with a user mental model), it leads to “Cognitive Friction” (Cooper, 2004).

The “Cognitive Friction” is a by-product of the information age, and it is more evident in all the computing devices lacking a natural cause-effect relation between user input and device output, e.g. when similar inputs result in different outputs.

When a person is dealing with the cognitive friction, ancestral mechanisms of the human being come into play. As result, in this case, users cannot be modeled as purely rational beings. Thus, to understand users’ behavior, and to appreciate how systems can be made usable, we need to consider the following factors:

- Users are driven by goals. People are naturally prone to pursuing goals. In achieving this, according to Krug “every question mark adds to our cognitive workload, distracting our attention from the task at hand” (Krug, 2005). This, according to Norman (Norman, 2002), creates usability issues, because it introduces the cognitive friction into play and leads users to make mistakes, which sometimes can also result into security flaws;
- Users do not read the instructions. Users proceed by trial and are not interested in reading manuals, instructions or documentation. For most of the users, it is not important to know how to do something, until the moment in which it is not necessary to use it (Krug, 2005);
- Users follow the path of least resistance. Several studies in the field of HCI have shown how users, in their task to accomplish a goal, tend to seek the path requiring them less effort (e.g. (Norman, 2002)). Once they find the first reasonable option allowing them to perform the desired action, it becomes irrelevant to them if it

is not the most efficient and safe option. Furthermore, users have no incentive to improve. When users “find something that works - no matter how badly – they tend not to look for a better way” (Krug, 2005). Some operations can be inconvenient from the point of view of performance, others, in the long run, can cause damage to the system: users may be unaware of it until problems show up for the first time.

While many research studies in HCI has been focused in defining what usability is and, consequently, intervene in improving user interfaces, several studies have shown that the “ease of use” cannot be limited to those aspects alone (Whitten & Tygar, 1999) (Balfanz & al., 2004).

To increase the acceptance of the security mechanisms, conventional wisdom suggests it is sufficient to make them easier through a more usable user interface. In practice, however, it is not enough to provide a proper user interface, even in the case it is supported by specific configuration guidelines. This is what Whitten and Tygar argue, in their study “Why Johnny cannot encrypt” (Whitten & Tygar, 1999), which is a seminar paper in the usable security literature. This study focuses on analyzing data and email encryption of the security software Pretty Good Privacy 5.0 (PGP). They showed that user errors have not decreased, despite years of improvements to the graphical interface. This has led to additional studies looking beyond the interfaces.

This field of study, which deals with analyzing the usability issues related to security, is called HCI-Sec and was founded in 2000 by Whitten as a mailing list on Yahoo! Groups. It has been said that HCI-Sec “only rarely received significant attention as a primary subject for study” (Balfanz & al., 2004), this despite the fact that “usability remains one of the most pressing and challenging problems for computer security” (Whitten & Tygar, 1999).

Although HCI-Sec has only recently gained momentum, initial studies have their roots in 1975,

when (Saltzer & Schroeder, 1975) argued that the usability was an essential component of a secure system. In their seminar “The protection of Information in Computer System” they presented eight basic principles that serve as guidelines for the design of systems aimed at protecting information. The principle of the “Psychological Acceptability” is one of them, and states: “it is essential that the human interface is designed for ease of use so that users routinely and automatically apply the protection mechanisms correctly”.

Since then, little work has been focused on HCI-Sec and, as a result, the security systems are sometimes poorly designed, leading to cases where users seek alternative interactions with the system or completely avoid the security mechanisms. Given the difficulty in making IT systems usable, it is unsurprising that the problem of “aligning usability and security” has been almost neglected until the beginning of the early 90s of the last century.

According to Fléchaïs, it is wrong to justify such a dearth of research as a tension between usability and security. Until that decade, the research community was more focused on technical trade-offs, such as for example the realization of robust encryption on low energy consumption microprocessors (Flechaïs & Sasse, 2005). This is reasonable, because, before the growth of the Internet, security was mainly a physical concern, and physical thinking was based on a military mindset.

The problem of usability in security, however, was not limited to this, and already existed during the 80s and 90s. For example, it was already possible to improve usability and possibly weaken security by automating common tasks. Brad Reid (Reid, 1987), argued that programmer convenience is the antithesis of security because it becomes intruder convenience if the programmer’s account is compromised. Reid mentioned a “programmer” because at that time the main users of the computer systems were mostly researchers or computer science specialists who possessed some programming aptitude. These individuals

possessed technical skills, received specific training and were, therefore, prone to ignore usability, and failing to identify the security implications this might have.

In the 1990s, with the diffusion of personal computers and the mass adoption of the Internet, the problem of usable security has remained virtually unexplored and did not leverage pre-existing HCI research. The initial solution to the problem addressed the symptoms rather than the root cause, by updating the anti-virus software, or the patching software in known problems. Therefore, research has been focused more on short-term practical gains, rather than long-term design changes that attend to both usability and security. A further problem is that few developers are trained in usability, or have significant software security experience.

The advent of HCI-Sec introduced the idea of security as an important consideration for usability, while usability is an important aspect of security (Cranor & Garfinkel, 2005). Therefore, if the purpose of HCI was to ensure that users would reach their goals by the use of better interfaces, HCI-Sec aims to ensure that users are able to achieve these goals also in the most secure way.

MAIN FOCUS OF THE CHAPTER

The aim of this chapter is to analyze the goals and state of the art of usability and security to determine where and how they can be effectively “aligned”.

ISSUES, CONTROVERSIES, PROBLEMS

Usability has become a key factor in the quality of the software and has a determining role in productivity and acceptance (Cranor & Garfinkel, 2005). This term has more than one meaning, though; it refers multiple concepts that may or may not be taken together. Some are based on *execution time*, *performance*, *user satisfaction* and *ease of learn-*

Figure 1. Usability definitions according to ISO/IEC 9241-11, ISO/IEC 9126 and ISO/IEC 25010

ing (also known as *learnability*). Thus, it remains something that is not unequivocally defined, and is subject to interpretation based on the stake one has in usability (Hertzum, 2010).

Over the years, the International Organization for Standardization (ISO) itself produced various, and sometimes conflicting, definitions of usability (Figure 1). These definitions can be classified into two main categories: *product-oriented* and *process-oriented*. The former category provides definitions of the qualities that belong to the final product. This appears to be a reasonable approach, because software usability is essential for end-users, as crucial for achieving particular tasks quickly and effectively. The latter category focuses on the methodological aspects of obtaining usability: for a software developer, usability describes the internal attributes of a system, including concerns such as quality of design, documentation, and maintenance.

These various points of view and the different requirements have resulted in contrasting perspectives on usability, carried out by several groups

of experts in a non-uniform and inconsistent way. For example, some terms have different meanings and labels. In document ISO/IEC 9241-11 (ISO, 1998) *learnability*, as a quality of a software, is designed as the “time of learning”, while in ISO/IEC 9126 (ISO, 2012) is defined as “comprehensible input and output, instruction readiness, messages readiness”.

Discrepancies among the standard can be even more significant: in the standard ISO/IEC 9126, usability is defined in a product-oriented way as a set of attributes that bear on the effort needed for use and on the individual assessment of such use, by a stated or implied set of users. The qualitative properties to be achieved are Understandability, Learnability, Operability, Attractiveness and Usability compliance (Abran & al, 2003). The standard that replaced it, ISO/IEC 25010, focuses on the user’s goals and on how fast they are achieved, in addition to user satisfaction with the system. In this document, usability replaces learnability property in favour of *operability* (Lew & Olsina, 2010), which is described as the degree

to which the product has attributes that enable it to be understood, to be learned, to be used, and to be attractive to the user, when used under specific conditions.

With this definition of operability, the properties to be achieved are *appropriateness, recognisability, ease of use, learnability, attractiveness, technical accessibility* and *compliance*. The same standard describes however also a different model, *Quality in Use*, in which the usability appears described as the extent to which a product can be used by specific users to achieve specified goals with effectiveness, efficiency and satisfaction without adverse consequences in a specified context of use.

The process-oriented point of view was defined in the document ISO/IEC 9241, which is a suite of international standards on “Ergonomics of Human System Interaction”. In Part 11, the definitions of usability from different perspectives are grouped together. The key components are effectiveness and satisfaction. The former describes the interactions from the point of view of process efficiency and puts the focus on the results and valuable assets. The latter requires carefulness on the user’s needs. The standard attempts to explain how to identify the information that has to be taken into account when evaluating usability in terms of measures of user performance and user satisfaction.

The criterion of satisfaction is very difficult to be measured and, for this reason, additional usability factors have been proposed in Part 2 of ISO/IEC 25010. They are *likeability, pleasurable, comfort and trust*.

Given the subjectivity and the different contexts in which the term “usability” can be used, Kainda and Flechais (Kainda et al., 2010) proposed to consolidate it in six key factors which are defined as:

- **Effectiveness:** A system is only usable if its users can achieve intended goals, and effectiveness is measured by whether users are able to complete a particular task or not;

- **Satisfaction:** A system must be accepted by users, otherwise it is bound to fail, even if is usable;
- **Accuracy:** A system demands may have an impact on the user’s tasks. For example, a system may require 100% accuracy in an providing information, such as a pin code or a password. However, this accuracy, is not always achievable by the user, making the system unusable;
- **Efficiency:** To guarantee usability, a system must ensure that each user’s goals are achievable within an acceptable amount of time and effort;
- **Memorability:** A system may require users to memorize secrets, namely passwords. This may be problematic since the users are cognitively burdened with credentials, and other secrets;
- **Knowledge:** This corresponds to the Learnability property. However, the user may not attempt to learn or understand the system, as users tend to care only about the parts of the system of interest to them. Therefore, knowledge of the security mechanisms or policies is required by the user;

These characteristics can be measured in different ways. Effectiveness, satisfaction, efficiency and memorability can be measured directly, while accuracy and knowledge are measured indirectly, i.e. the first set of characteristics can be measured directly by quite simple empirical indicators, while the latter are typically derived by combining more indicators.

Another HCI-sec problem is that adequate usability is essential in specific security mechanism (e.g. authentication process), but the requirements for achieving it and a high level of security may collide (Braz & Robert, 2006). For example, in the case of password-based authentication, many usability principles (e.g. use shortcuts in case of frequent use, provide informative feedback)

contrast with best practices (e.g. password must not be showed during typing, and only success or failure must be reported, to mitigate social engineering and guessing).

SOLUTIONS AND RECOMMENDATIONS

From the perspective of HCI, there are several principles for building a system that is “quick to use and relatively error-free” (Johnson, 2007). One of the most important of these is ensuring the system “does what the user wants” without “complicating the user’s task”. Another important aspect is to evaluate the usability of a system. In this regard, the System Usability Scale (SUS) (Brooke, 1996) is a widely accepted base. The SUS is designed to give a quick impression of the overall usability of a product. It consists of ten questions (e.g. “I found this system unnecessarily complex”, “I found the various functions in this system were well integrated”) rated on a Likert scale, resulting in an overall 0-100 value, where 100 represents excellent levels of usability. SUS has been adopted in many contexts, also in HCI-sec (De Witt, J. Kuljis, 2006) since quick to complete, thus avoiding user frustration and ensure answer accuracy.

From the perspective of methods and procedures used in HCI, many of them have been adapted to the HCI-Sec. The main difference is the focus on a balanced trade-off between usability and security.

The methodologies between HCI and HCI-Sec differ for at least five key aspects that are analyzed in the following paragraphs, detailing related recommendation as well.

THE SECONDARY GOAL

People do not generally sit at their computers wanting to manage their security; rather they want to send mail, browse web pages or download software.

Traditionally, security definitions have been defined around attackers. Unfortunately, doing so ignores the legitimate and non-malicious use, and also may adversely affect the system (Kainda & al, 2010). Users may not have the perception of damaging the system or, through making certain actions or inactions, bypassing security systems, putting their assets risk. Users must be constantly made aware of the operations involving security and the system must ensure that it is hard to make catastrophic errors. Furthermore, if such events occur, user actions should be reversible. To illustrate how this can be achieved, consider the implementation of dialog boxes requiring confirmation of a particular action. The implementation of the “Empty Trash” feature in desktop operating systems typically allows accidentally deleted files to be recovered, or the “Undo” button, now present in many desktop applications, allows for an action to be reverted. In a business setting, backup and redundancy of servers are amongst the systems used to avoid potential damages even from non-malicious users. Unfortunately, as Garfinkel has demonstrated, even “Empty Trash” functionality can behave in a manner inconsistent with a corresponding interface design (Garfinkel, 2005).

ABSTRACTION

Security policies are usually phrased as abstract rules that are easily understood by programmers but “alien” and unintuitive to many members of the wider user population.

(Johnson, 2007) proposes a focus on learnability and memorability, properties which, as we have discussed, belong to Usability. Facilitating the learning process is possible, by creating a consistent lexicon transmitted through the user interface. This is convenient since it was discovered that a particular trend also applies to IT users: they prefer not to invest time in training or reading manuals, but in learning the functionality of the system through the exploration of the user interface (Krug, 2005).

THE HIDDEN FAILURE

It is difficult to provide good feedback for security management and configuration because configurations are complex and not easy to summarize.

Making a secure system does not guarantee its security because the system must also be installed and used in a secure way. (Bishop, 2005) noted that the configuration is a key component of security because it is during the configuration of a system that it is defined who will interact with the system and how. Practitioners and security staff often make mistakes in applying default software configurations, ignoring the fact that different configurations lead to different security contexts. For example, a computer configured to be secure in a university research environment could be considered insecure in a military installation. In the former, information might be made accessible to the whole class or research group while, in the latter, they might be accessible only on a need to know basis.

One method used to counteract and minimize the adverse effects of an incorrect configuration is the "fail-safe default" principle (Saltzer & Schroeder, 1975). This states that the safest solution is a default configuration without any permission granted. During the configuration phase, a security responsible task selects the correct permissions for each system function and group of users. When configuring a firewall, this principle corresponds to the whitelist configuration: everything that is not explicitly allowed is forbidden by default. This policy contrasts with the blacklist, which grants any permission by default and chooses specifically the ones to forbid. The former one, despite being more difficult to handle, forces discussion on any permission to be enabled, thereby making the system more secure.

THE BARN DOOR

Once a secret has been left accidentally unprotected, even for a short time, there's no way to be sure it has not already been read by an attacker.

Once sensitive data or vital assets for the company are compromised and made public by mistake, it is possible that attackers will use it for their own advantage. There are several ways to approach this problem. You might try to avoid social engineering attacks, where even expert users fall victim to if channels of communication they trust and use regularly are compromised. This risk can be prevented using anti-fraud mechanisms, aimed at preventing phishing through e-mail or other channels. Should an attacker successfully obtain sensitive information such as passwords, private keys or credit card numbers, it should also be possible to erase and getting new information. In the case of commercially sensitive intellectual property, DRM can also be implemented, which can control access to resources, and revoke permissions in the event of a successful attack. DRM technology is, however, complex to maintain and not without its own usability issues (Favale & al., 2016)

THE WEAKEST LINK

The security of a networked computer is like a chain: it is only as strong as its weakest component.

It is generally recognized that the user is often the weak point of a computer system from a security perspective. However, as discussed, this creates a vicious circle in which users are kept unaware of what the security mechanisms are. Therefore, users are driven to the creation of their own security views, which fail to align with reality. To avoid this issue, security mechanisms should be complemented by specific guidelines that take into account the specific constraints of security mechanisms, minimizing discrepancies introduced by users with different backgrounds and skills.

FUTURE RESEARCH DIRECTIONS

Future research direction will address the problem of measuring usable security in a more systematic and practical way, or, as a first milestone toward the goal, understand if there are real advantages and tangible benefits resulting from formative and summative usability assessment processes. Such an assessment is not easy because of the previously discussed complex variables into play. Moreover, there are several aspects that are influenced by contextual conditions, such as economic resources, time, and other economic or innovation drivers.

To address these evaluation issues, we need to understand what it means to precisely evaluate usable security. Only then will it be possible to identify what methods can be effectively used in the analysis processes.

Also, all these facets activate different levels of sub-choices that depend on several variables and the context of use. One of these could, for example, be advancing the project in time: do you want to evaluate a system in its initial stage of development, or at a different iteration of the same application? It has already been noted that, while considering security at an early stage of a software product's design is virtuous, design techniques may be needed that specifically consider security at a later stage (Faily, 2015).

For any improvements, development should be scientifically measurable. As Lord Kevin said over 200 years ago "if you cannot measure it, you cannot improve it", meaning that without a scientifically sound evaluation methodology, would be difficult to draw any objective conclusions and take any proper improving actions (Atzeni & Liroy, 2005).

Measurement should not be an end in itself, but lead to something analogous to a benchmark, which is a result or a group of results that can become a point of reference and standard; this enables comparison and judgment on how good or bad things are.

CONCLUSION

Human behavior is goal-driven, therefore each aspect of a system interacting with users, security included, should be organized to help users to achieve their goals. In particular, security must be embedded paying attention to usability aspects, to avoid "cognitive friction".

Since usable security principles can be applied both to final product and to the production process, from one hand it is necessary to adopt methodologies to understand and measure the usability of the final artifact, from the other, all production line components should be considered in light of usability effectiveness, starting from the earliest steps in building software. This ensures that the quality of usable security is 'built into' the final product, and diagnose the feedback that allows the project to be changed before its final release.

The ability to diagnose and correct an error in the usability of a software before entering the market is in itself a significant benefit, as are methods that can also be used to determine quality variations between two iterations of a given software. It is, therefore, necessary to describe and scientifically evaluate the properties of usability and security as two correlated factors, even if they are both difficult to quantify and even define. To facilitate quantification and definition, past literature split up usability and usable security in more atomic pieces (e.g. effectiveness, satisfaction, accuracy, efficiency, memorability) to make them more identifiable and comparable.

Finally, a scientifically sound usability assessment is a target of great interest. Further research is welcome because it is a complex problem (even when decomposed in sub-parts like satisfaction or memorability) and because the context of a product under evaluation can introduce influencing variables, enlarging the problem complexity.

KEY TERMS AND DEFINITIONS

Cognitive Friction: The affinity friction between the user and the software that originates in the user mind when a product does not behave the way the user expects (e.g. a button on the screen that does not trigger any action when the user press it). (<https://www.linkedin.com/pulse/20140801230851-205508682-what-the-heck-is-cognitive-friction>).

Comfort (ISO/IEC 25010): The extent to which the user is satisfied with physical comfort.

Effectiveness: The properties which measures to what extent interactions achieve objective process efficiency indicators (i.e. concrete results of user actions while using the addressed product).

Likeability (ISO/IEC 25010): The extent to which the user perceives achievement of pragmatic goals, including successful subjective results of use and consequences of use.

Memorability: A factor which measures how much a product require users to memorize secrets (e.g. passwords or passphrases).

Operability: The degree to which the product has attributes that enable it to be understood, be learned, be used and be attractive to the user, when used under specific conditions.

Pleasurable (ISO/IEC 25010): The extent to which the user is satisfied with his perceived achievement of hedonistic goals of stimulation, identification and evocation and associated emotion responses.

Psychological Acceptability: A founding principle of usable security stating that “*it is essential that the human interface is designed for ease of use so that users routinely and automatically apply the protection mechanisms correctly*”.

Process-Oriented Usability: The categorization of usability aiming to achieve it addressing the characteristics of the process to obtain the final product (e.g. documentation and design effort).

Product-Oriented Usability: The categorization of usability aiming to achieve it addressing the final products characteristics (e.g. learning curve to use the product).

Satisfaction: The property which measures to what extent the user's needs are subjectively satisfied by the product.

Trust (ISO/IEC 25010): The extent to which the user is persuaded that the product will behave as intended.

Knowledge Management

Boosting the Social Development of the Majority Through the Creation of a Wireless Knowledge Society

K

Danilo Piaggese
Framericas, USA

INTRODUCTION

The rapid advances and pervasive diffusion of information and communication technology (ICT), combined with the growth of the wireless Internet, has led to deep transformations in economic, social and institutional structures. ICT applications affect the performance of businesses and the efficiency of markets, foster the empowerment of citizens and communities as well as their access to knowledge, and contribute to strengthening and redefining governance processes at all institutional levels. Nevertheless, as all major and wide-ranging technological advances, the deployment of ICT is at the same time creating enormous opportunities and posing daunting challenges to the Majority in the emerging economies (EE).

According to C.K. Prahalad (2005) in his book, *The Fortune at the Bottom the Pyramid*, “The distribution of wealth and the capacity to generate incomes in the world can be captured in the form of an economic pyramid. At the top of the pyramid are the wealthy, with numerous opportunities for generating high levels of income. More than 4 billion live at the Base of the Pyramid (BOP), on less than \$2 per day. Those are the Majority.”

This paper presents some of the successful sustainable ICT practices aiming at boosting the social development of the Majority contributing to the creation of a wireless and inclusive Knowledge Society. It also offers a road map for the international financial institutions, particularly the Multilateral Development Banks (MDBs), aiming at supporting ICT for development programs benefitting EE.

DOI: 10.4018/978-1-5225-2255-3.ch434

BACKGROUND

The United Nations Millennium Declaration (United Nations, n.d.) noted that efforts to make internet access available to all and to harness the power of ICT could contribute toward the achievement of the Millennium Development Goals (MDGs), thereby creating “digital opportunities” in development. The ongoing debate on the new set of UN Sustainable Development Goals (SDGs) reignites the interest for the ICT in a contest of emerging knowledge economies and societies.

The ICT can facilitate the participation of lower income populations, the majority at the base of the pyramid, according to the definition given in (Prahalad, 2005) in the development process by directly tackling relevant aspects, which precisely hinder their integration into social and economic development. Such aspects concern:

- Limited knowledge and literacy which impairs access to skills and jobs (education);
- Poor health and sanitary conditions limiting employability and risk-taking attitudes (health);
- Scarcity of economic opportunities (economy);
- Limited involvement in civic life and in the democratic processes, as well as uneasy access to public services (government).

The following successful sustainable practices, show how ICT can help reducing the risks of exclusion related to the aspects cited above, thus contributing to the integration of lower income

populations into social and economic development. Based on the lesson learned from the practices, we draw some conclusions and offer some recommendations. These recommendations are the basis for forward-looking scenarios that can be realized through the deployment of ICT towards the attainment of an inclusive economic growth process for all, meeting social development and poverty reduction objectives, as expressed in the United Nations Millennium Declaration.

SUSTAINABLE PRACTICES IN ICT FOR SOCIAL DEVELOPMENT AND POVERTY REDUCTION

ICT in Human Capital Development

Inequalities in access to education—especially high-quality education that prepares young people for employment opportunities in an inclusive knowledge society and to become active citizens in complex, market-driven, democratic societies—are a critical barrier to reducing poverty and increasing economic growth. Near-universal access to the Internet via low-cost networks enables teacher training, enhances student access to traditional teaching materials via Internet distribution, and allows the introduction and use of new and advanced multi-media resources and learning tools. The young generation takes readily to computers and such resources, and there is

evidence that classroom access to ICT tools can improve learning and help motivate students to stay in school.

Best practices for ICT-enhanced classroom education have been slow to emerge, in part because of the high cost of providing computers, appropriate curricula and adequate teacher training. Nevertheless, there are a number of concrete examples that show the effectiveness of widespread, small-scale experimentation and pilot projects which, coupled with careful evaluation, provide best practice ICT applications for formal and informal education (see Table 1)

ICT in Health and Social Services

The improvement in the delivery of health care services in geographically remote and rural areas is one of the most promising and clearly demonstrated applications of ICT in social development. Evidence suggests that improved health outcomes have been achieved through various applications of ICT solutions. In particular, ICT is being used in many developing countries and communities to facilitate: (a) remote consultation, diagnosis and treatment through the use of digital cameras to download images onto a computer and transfer them to doctors in nearby towns; (b) collaboration and information exchange among physicians; (c) ICT-based medical research through the use a network of satellites and ground stations to submit data for clinical trials; (d) medical training through

Table 1. Committee to democratize information and communication technology in Brazil

The <i>Comitê para Democratização da Informática</i> (CDI), a nongovernmental, nonprofit organization fosters the social inclusion of less-privileged social groups with ICT as a tool to encourage education and active citizenship. It works to create opportunities for young people to free themselves from poverty and social exclusion through the implementation of community Computer Science and Citizenship Schools (EICs). The CDI views computer literacy as a vehicle for creating employment opportunities and promoting civic participation, formal education, literacy, concern for the ecology, health, human rights, and nonviolence. The CDI also uses ICT to benefit low-income communities and institutions by assisting individuals with special needs (including the physically and mentally disabled, the visually impaired, homeless children, prisoners, and indigenous populations). CDI invests in the community's capacity to organize its own educational programs. Since its inception in Rio de Janeiro in 1995, CDI has provided support to 130 communities in the establishment of autonomous and financially self-sustaining EICs. In order to promote digital inclusion, CDI entered into partnerships with national and international philanthropic organizations, companies, government agencies and individual donors. There are currently 965 EICs using the methodology and model developed by CDI. In a recent evaluation, carried out by an external consulting group, 86 percent of the students stated that CDI schools had a positive impact on their lives (such as going back to regular schools, making new friends and staying away from drugs). The experience has been replicated throughout the world and, today, CDIs operate in Argentina, Chile, Colombia, Guatemala, Honduras, Mexico and Uruguay as well as in Angola, Japan and South Africa.

ICT-enabled delivery mechanisms; and (e) access to centralized data repositories connected to ICT networks that enable remote healthcare professionals to keep abreast of medical knowledge.

Moreover, ICT provides considerable benefits and capabilities when applied to disease prevention and response efforts during epidemics (see Table 2).

As far as the social services are concerned, it is important to mention the CETID project, a successful good practice of the State of Sao Paulo, Brazil, for the social inclusion of people with disabilities through ICT. CETID stands for “Center of Excellence in Technology and Innovation for the social inclusion of people with Disabilities”. This successful practice is the result of the Knowledge economy approach to the activities of the “Sao Paulo State Secretariat for the rights of people with disabilities”. By the simultaneous and seamless investments in Innovation, Education, ICT, Habilitating policies and Institutional regimes, the Secretariat created a virtuous cycle that led to the creation of the Center that benefits people with disabilities.

ICT in Financial Services

ICT tools can drive down transactions costs for financial services such as microfinance and a widening range of banking, insurance, and other services for low-income groups, particularly as their delivery expands beyond nonprofit groups

and becomes more widespread (see Table 3). For example, the expanded use of ICT and the Internet can reduce the transaction costs of remittances in a way that brings higher social benefits for all parties involved in these transactions. Nonetheless, there is still much to do. Transaction systems adapted to serve low-income communities via text messaging over mobile phones have been successful in Asia and Africa, and may prove useful in Latin America and the Caribbean as well. ICT offers several approaches to expanding access to electronic transactions and banking services via remote transaction devices for microfinance that work over mobile phone networks; smart cards that can store account balances, transaction histories, and positive IDs such as a fingerprint. The next generation of mobile phones and bank services are capable of conducting transactions automatically via very short-range radio, potentially turning phones into electronic wallets.

Wireless Technologies and Community-Based Communications Services

Largely for reasons of cost, most rural communities and many low-income urban communities lack effective and affordable local phone systems. These communities usually rely on a few pay phones or shared mobile phones (which are used sparingly) and most calls are made to numbers outside the community. Yet historically, where affordable lo-

Table 2. Alerta DISAMAR: an innovative disease surveillance system in Peru

Real-time reporting of disease outbreaks as well as ordering medicines and supplies via software such as the VOXIVA toolset pioneered in Peru (which is now used worldwide) has dramatically increased the efficiency of health services delivery. Such solutions combined with handheld devices assist frontline health workers in efficiently collecting and reporting patient data, and contain digital diagnostic and treatment guides for a wide variety of conditions. Alerta DISAMAR is a pilot disease surveillance program implemented in 2002 by the Peruvian Navy, which relies on novel technology from VOXIVA Inc. Alerta DISAMAR allows users to collect, store, disseminate and analyze data on diseases under surveillance, reported through any type of telephone or the Internet. Designated users receive automatic notification of selected reports via e-mail, voice mail, or SMS message. Health officials can communicate with remote health professionals using voice mail as if they were e-mails to individuals or to predetermined groups of users. The system sends timely automatic reports on the number of cases of eight of the most reported diseases compared to the previous three weeks and a monitoring of cases that do not have yet a final diagnosis. Alerta DISAMAR shows a sustained improvement in coverage, data quality, baseline incidence rates, and outbreak detection capability. Alerta is a flexible and stable program with minimal recurring costs. It is a prime example of sustainable technology transfer for improving public health in a country with limited resources. More than 18,042 health events have been reported so far using this program. In addition, 18 outbreaks have been detected that have led to recommendations for improving vector control and food procurement processes.

Table 3. PRODEM FFP's multilingual smart ATMs for microfinance in Bolivia

Bolivian PRODEM Private Financial Fund (PRODEM FFP) offers low-income communities and micro, small and medium enterprises a wide range of savings, credit and money transfer services. Its 65-branch network is the largest in the country and spans both urban and rural areas. To expand its market, improve its services in even the most remote areas and help overcome barriers such as illiteracy, the company has developed and deployed a new technology-based solution that employs smart cards, digital fingerprint recognition technology, and Smart ATMs, as well as stand-alone, voice-driven Smart ATMs in local languages with color-coded touch screens.

cal phone systems exist, typically 60 percent of all phone traffic is within the community. Thereby, a low-cost local phone system can make universal access a reality in many communities of EE (see Table 4).

The technological potential of the project has emerged, via local Wireless Fidelity Networks (WiFi) and Voice-Over-Internet (VOIP) telephony using peer-to-peer systems. For example, technologies such as Skype are having a global impact on long distance calling. In addition to making a wide range of voice-driven e-government and commercial services accessible and affordable, low-cost wireless networks, VOIP and high-capacity broadband networks, enable access to a great variety of Internet services and information via a computer or other converged device.

One of the benefits of voice-driven or voice-accessible services—especially if also made available in indigenous languages—is overcoming literacy and computer skill barriers. Other benefits also include ending rural isolation, enhanced family solidarity, increased access to information and services, improved ability to find employment and, at a community level, higher economic capacity and productivity and wider citizen participation in

democratic processes. The experience shows that this can be achieved with affordable computers and Internet access, especially if these services are delivered through local entrepreneurs or community access facilities that can assist in computer and Internet usage.

Nevertheless, not all the countries in Latin America and the Caribbean (LAC) have made VOIP legal or removed restrictions to its use. Likewise, few countries have made frequencies available for unrestricted WiFi use, permitted open competition for telecom and Internet services, or allowed community-based systems exemption from legal/natural monopolies. Beyond regulatory restrictions, the business environment in many countries still poses barriers to entrepreneurs and the creation of small businesses. There have been few pilot projects that promote best practices with rapidly emerging ICT technologies such as those cited. As a result, the LAC Region still lags behind many Asian, and even some African countries in realizing the potential development benefits from widespread ICT access and emerging wireless and no conventional communication technologies (see Table 5).

Table 4. Communications and social services in the Amazon

The Amazon Association, a Brazilian NGO, and the Solar Electric Light Fund, a nonprofit organization based in Washington, D.C., teamed up to provide basic services and economic opportunities to the Caboclo Indians by means of broadband wireless Internet. Many members of this indigenous community lack basic health care, education and economic opportunities. In the absence of phones, electricity or Internet infrastructure, solar panels are being used to power a permanent satellite uplink to a local telecenter, which was built in four days and is expected to be self-sustainable in four years. In addition, it is expected that connectivity will be extended to other communities along the Jauaperí River in a cost effective manner by using WiFi technologies and sharing costs. According to the Wireless Internet Institute, “communicating on a regular basis with the outside world has provided a tremendous psychological lift to the community.” The Amazon Association is able to stay in contact with community members via e-mail, reports on problems at the reserve, participates in decision-making, and requests supplies and medicines. Wireless technologies are an important means for outreach, empowering a community and promoting civic involvement. The project has become a source of income for local craftswomen, who can now sell their wares through the Amazon Association.
--

Table 5. Vodacom's community cell phones in South Africa

Vodacom Community Services started operating under a 1994 government mandate to provide telecommunications services in disadvantaged communities in South Africa. Vodacom developed an innovative way to meet this mandate, via entrepreneur-owned and operated phone shops. These have provided affordable communication services to millions of South Africans, and empowered thousands of previously disadvantaged individuals with income-generating opportunities and lasting business skills. The Community Services program now provides over 23,000 cellular lines at over 4,400 locations throughout South Africa. By investing so extensively in disadvantaged communities, Vodacom is also investing in its own future by creating a distribution channel for its services, in addition to a well-recognized brand name. Though full returns will materialize in the future, the company is confident that its investments will pay off directly through increased sales and indirectly through a stronger, better-connected South African economy.

A WIRELESS KNOWLEDGE SOCIETY¹

Table 5 illustrates what Professor C. K. Prahalad of the Michigan Business School poses in his book *The Fortune at the Bottom of the Pyramid: Eradicating Poverty Through Profits*, which highlights the collective purchasing power potential of the world's 4 to 5 billion poorest people (the Majority). He urges efforts to promote an enabling business climate that goes beyond the promotion of social corporate responsibility as means to foster local well-being, while generating a strong revenue and profit potential base in the long term. Moreover, a recent study by the London Business School found that, in a typical developing country, an increase of ten mobile phones per 100 people boosts GDP growth by 0.6 percentage points. The study concludes that wireless solutions are concrete examples of "technologies that help people help themselves" (Avgerou, Ciborra, Cordella, Kallinikos, & Smith, 2005) by: promoting a multi-stakeholder partnership framework delineating the effective participation of the public sector and civil society, while creating the incentives for socially responsible private investment; strengthening the provision of ICT-based public social services and promoting social inclusion, while maintaining the role of the private sector as the main source of innovation; stimulating macroeconomic growth by facilitating access to knowledge and information through increased connectivity and appropriate ICT solutions for marginalized and lower-income populations, thereby tapping a strong market potential; designing and adopting long-term ICT investment frameworks in human development.

By removing barriers to the entry of new and lower-cost technologies (such as fixed wireless) and of new communication and ICT-based services (such as Voice-Over-Internet phone service), and ensuring open competition, it will be possible to increase entrepreneurial activity and expand private sector investment. Nevertheless, the direct involvement of the public sector continues to be fundamental in sharing and expanding service into remote areas and to serve as a catalyst for the effective delivery of social services. This also reduces risk for private enterprises and helps comply with commitments to serve certain regions, communities and marginalized or disadvantaged groups, while also allowing market forces to trigger actions and operate effectively.

The World Summit on the Information Society (WSIS) asserted the importance of the use of information and communication technologies (ICTs) for the achievement of the Millennium Development Goals (MDGs).²

In particular, wireless Internet technologies deserve particular attention not only because of their importance to the development process, but also because of their ability to reduce the costs of providing ICT access and ICT-enabled services to underserved areas.

The cost of providing access to voice and data networks using wireless technologies, even in rural areas, approached in 2005 US\$300 per subscriber, compared to US\$1,000 for fiber optic or copper networks in urban areas. In addition, wireless technology does not imply significant sacrifices in quality or throughput. Furthermore, while copper or fiber optics usually cost between US\$20,000 and US\$40,000 per kilometer of

connectivity, hundreds of kilometers of wireless connectivity can be provided for US\$50,000 (Best, 2003). This cost advantage (which is widening with increasing global use of wireless technologies and resulting economies of scale) can be used to connect rural areas in a cost-effective and even self-sustainable fashion.

Given its unprecedented cost advantages wireless technologies promise more than a cost-effective way of providing access to underserved populations. For governments, wireless technologies offer a way to deliver valuable services (such as health and education), as well as government services, to citizens living in remote areas.³ In some cases, rural populations can pay for the capital costs of any necessary equipment as well as the recurring costs of Internet connection. For example, poor rural residents of Tamil Nadu, India, have funded telecenters for as little as US\$3 in revenue per day by using a wireless technology similar to WiMax called corDECT. An analysis of Latin America and the Caribbean shows that the same could be accomplished in the region for approximately US\$3 to US\$14, covering between 100 and 500 households. Recurring monthly costs for wireless Internet connectivity for education purposes in Sucre, Colombia, amount to US\$5 per student per year. The latent demand for communication services from poor rural populations could bring financing and sustainability even without government aid. The following examples from selected EE countries provide a broad picture of possible successful wireless applications:

Providing Education in Sucre, Colombia

The state of Sucre is marked by high poverty and illiteracy rates and, until some years ago, uncontrolled violence. After security was re-established, population increased by 30 percent without a commensurate increase in the state budget. The *Corporación Politécnica Nacional de Colombia*, a partnership between the government

and the private sector, was created in an attempt to control high school dropout rates and improve the cost-effectiveness of education.⁴

Through a grant (that is considered a social investment) from the Ministry of Education for approximately US\$220,000, the *Politécnica* connected 11 schools across the state using wireless technologies, provided new computers, and trained local staff at each school in hardware and LAN maintenance. Recurring costs of the Internet connection, software upgrades, ISP uplink costs, and network infrastructure amount to US\$5 per student per year, which, so far, has been funded by the state government.

The initial response was not as good as expected. The availability of Internet did not by itself promote its use, and neither did the services offered when the project was launched. However, after adding customized services, including course management software as well as human and capital resources, software usage increased. Students and professors have reacted very positively to the Internet connection and the software, and they now routinely create websites and participate in classes via videoconferences from state universities. This experience shows that simply providing Internet connections is not enough to promote its usage or address development problems. In addition to providing connectivity, investments should be made to develop customized services.

Voice and Services in the Dominican Republic

A village-area network (VAN) was installed in Bohechio, Dominican Republic, in March 2001 as part of the LINCOS project headed by the Costa Rican Foundation for Sustainable Development. The rural community of Bohechio, one of the least developed communities in the country, is situated in a mountain range and has a population of approximately 7,000 people (Best, 2003).

The VAN covers an area of approximately one square kilometer and took three days to install.

The cost was less than US\$20,000 (prices fell significantly in recent years) for six computers, two telephones, a multifunction fax/scanner/ printer, a cash machine, an environmental testing lab, FM radio station broadcasting ability, a big-screen TV, and a telemedicine unit. A VSAT provides uplink connectivity via satellite link and, using an 802.11b network, gives access to wireless devices, including PDAs and voice- over-IP telephones at a radius of up to 1 kilometer and at speeds of up to 11 Mbit/second (Best, 2003).

Applications currently provide assistance to schools, a medical clinic and farmers. The VoIP solution and associated IP-based telephones installed around the town compete with the telecom provider, offering rates of US\$0.18 per minute on calls to the city, compared to US\$0.30 on fixed lines. INDOTEL, the national telecommunications regulatory authority, has relaxed its regulations so that spectrum used in the project is valid and has offered significant support and partnership (Best, 2003).

E-Commerce in Ecuador

The “world’s first Wi-Fi linked e-payments network” was created in the Mall of San Marino in Guayaquil, Ecuador, through a partnership between the US e-payments equipment and services provider, Verifone, and the wireless equipment provider MediaNet, a subsidiary of D-Link. The wireless network eliminated multiple dial-up phone lines and Internet access points, using instead a central uplink and IP- based Wi-Fi to connect Verifone’s “multimodal network access point-of-sale terminals” in the stores. This resulted in lower charges for long- distance calls for merchants and 24-hour/7-day availability. The speed at which payments were processed and data transferred improved by 350 percent, with an average of four seconds per transaction. Verifone’s marketing director for Latin America and the Caribbean stated that the company expects “wireless-enabled POS terminals to become more mainstream over the next several years, particu-

larly when the solution is delivered with the right partners” (Burger, 2004).

PDAs and E-Health in Uganda

Malaria, tuberculosis and AIDS have ravaged many African countries and have been largely responsible for the current health crisis in the continent. SATELLIFE, a Boston non-profit organization, has been using WideRay servers, rugged plastic boxes equipped with a GSM cell phone and Strong ARM processor in an effort to help ameliorate the critical situation.

Equipped with wireless-capable PDAs in rural areas in Uganda, health workers, many of whom had never used a computer before, are able to relay information to the Ugandan Ministry of Health on drugs needed by the population and local epidemics. The International Development Research Centre (2003) notes that, prior to this innovation, reports were hand written and requests for medicines took months to reach those able to fulfill them. The introduction of the PDAs has significantly reduced the time lag to receive needed medicines in rural areas, and has also made it possible to relay information back to healthcare workers in the field regarding the most cost-effective approaches or latest treatments for endemic diseases. In addition, reporting errors have been drastically reduced, improving the quality of the information available to policymakers. As a result of improved information on the health status and burden of disease of the population, important improvements can be expected in the management of national health budgets.

The application of these new low-cost technologies in Africa shows the type of improvements in social well-being that can be brought about by the use of wireless technologies. Like the example from the project in the Dominican Republic, this project demonstrates the success of using simpler technologies (i.e., PDAs with wireless) in cases where those involved may not know how to use computers.

E-Government in India⁵

Through e-government services a government can stay connected to remote populations and, with fee-based servicing, can ensure a steady stream of revenue so that local communities are able to run self-sustainable access points.

The Gyandoot project in the Dhar district of Madhya Pradesh established a set of telekiosks (small, self-service telecenters) that bring e-government services to the local population. The government has promised a one-week response time on local grievances for a fee of approximately US\$0.20. This has become the third most popular service, behind market prices and job availability (Best & Maclay, 2002). Additional services provided include assistance in obtaining legal certificates for land deeds, e-mail, village auctions, on-line matrimonial listings, and educational guides. Although most of the current network is based on wired infrastructure, wireless technology is being used to reach isolated and remote areas.

LESSONS LEARNED AND RECOMMENDATIONS

Based on the learning derived from the preceding examples and others, the following actions are suggested for the promotion and use of ICT for development:

- The creation or strengthening of the institutional capacity with the participation of the public, private and civil society sectors, in order to promote and foster the dissemination and use of ICT through programs and initiatives that build a participatory information and knowledge society.
- Raising awareness and creating the conditions for the design and implementation of pilot initiatives and the replication of best practices in priority areas including ICT for social development and poverty reduc-

tion, ICT for governance, and ICT for economic growth, among others.

- Undertaking the actions necessary to promote a digital inclusion for all.
- Creating the organizational conditions for the identification of concrete and comprehensive national ICT investment plans which effectively delineate the participation of the various sectors and stakeholders.
- Implementing and/or strengthening national and regional regulatory frameworks to, among others, promote competition and loosen restrictions on the telecommunications market, allow for the expansion of media convergence, and promote and facilitate research and technological innovation.

The Multi-Lateral Development Banks (MDBs) can play a relevant role in supporting ICT for development programs. Indeed, the MDBs are aware that they must continuously update their financial and technical assistance instruments to effectively adapt to the demand of their borrowing member countries; they have to support activities to provide and facilitate access to efficient ICT tools for the exchange of information, ideas and knowledge; and they have to support the deployment of ICT to promote a more inclusive socioeconomic development that extends benefits to the poor.

In particular, the MDBs could establish collaboration agreements with the technology-based private sector by taking into consideration:

- The extensive need for new and modern technologies in pilot and demonstrative projects, and whose results and applications can be replicated in operations of a wider scale.
- The goal to make the private sector from both, donor and borrowing member countries of the Banks, as active stakeholders in the development process through ICT.

- The aim to provide opportunities for the private sector to participate in the efforts of the countries towards social development and poverty reduction, while creating value added opportunities and the expansion of ICT-based services.
- The example of the Inter-American Development Bank (IADB) that created the “Facility in Information and Communication Technology for Development”, which set the institutional, financial and legal means for the Bank to effectively partner with leading private sector firms and civil society institutions with the goal of contributing to the attainment of the MDGs by the countries of the Region and, specifically, through the value added ICT solutions described above.

The MDBs have the opportunity to take a leadership role in shaping the enormous potential of wireless ICT in the EE. One overarching principle is that the MDBs should not in any way replace or hinder the significant efforts of the private sector. There are, therefore, four primary initiatives related to wireless technologies that the MDBs can lead: convening policy discussions across sectors, streamlining existing country operations through pilot projects, generating and sharing best practices, and fostering a regional policy consensus.

FUTURE RESEARCH DIRECTIONS

The hypothesis that ICT can have significant positive impact upon socio-economic development indicators is based generally on three propositions: (1) speed, because ICT are based on increasingly sophisticated digital instruments, and because rapidity of processing is one of their principal attributes, the use of ICT to deliver development services increases the speed at which those services become available to development beneficiaries; (2) reach, because ICT can make use of massive communication means, the number of potential

beneficiaries is greatly augmented; and (3) cost, as a function of a larger customer base and faster deployment rate, lower costs in the delivery of development services can be expected of the use of ICT as compared to other (traditional) instruments.

However, there is a significant gap between current and available knowledge regarding optimal conditions to make the most of the introduction of ICT to the development tool-box. In particular, the following research priorities have been identified:

- Impact and end-result (increase in income; number of direct and indirect beneficiaries; reduction in costs of service to the service provider, etc.) that depict more accurately the differential impact of the inclusion of ICT in a development context, capable of being adapted to different cultural and socio-economic settings;
- Development of cooperative arrangements to achieve critical mass in infrastructure (communications, R&D) investment available to the poorest countries, where conditions are not present to maximize the usefulness of ICT investment;
- Reliable, low cost, patent systems, particularly for communal, historic, or otherwise not individual innovation products;
- Effective communication mechanisms between supply and demand of ICT to cover the needs and acquisition ability of special interest groups and different income levels;
- ICT public policy needed to compensate market failures, and differential needs for low and medium income developing economies.

CONCLUSION

Examples of past programs, projects and activities where ICT has been instrumental to improve the conditions of beneficiary populations allow the following conclusions regarding the impact of ICT in a development context:

- ICT substantially lowers transaction costs in most economic activities;
- ICT increases the organizational capacity of private firms and their ability to manage data and information to base their decisions;
- ICT improves market effectiveness by broadening buyers and sellers' access to information –for example information on market price; volume, location and characteristics of demand; supply options;
- Investment in R&D explains up to 75% of the differences in total factor productivity growth rates, once externalities have been factored-in (Griliches, 1979, as cited in IADB, 2014), with productivity growth identified as a result, not a cause, of R&D investment (Rouvinen, 2001, as cited in IADB, 2014).
- In poorer countries, investment in R&D can have negative results due to the absence of trained human capital, apt scientific infrastructure, capable private sector, and effective public sector incentives.

In fact, in recent years, the EE have experienced a significant progress in the penetration of ICT, exceeding the growth achieved in the sector by other regions in the world. Nevertheless, the current levels continue to fall short of those in industrialized nations with respect to overall connectivity and widespread access, in addition to the adoption of ICT products and services by the private sector (especially by SMEs), as a means to improve their productivity, market access and overall competitiveness.

Priority actions have been identified in several fields: public policy; private sector investment; external financing; research; dissemination; among others. Success stories and case studies must attain wider audiences in order to make potential benefits of ICT for development a reality for lower income communities and countries. There is ample room for collaboration between higher and lower income economies in today's globalized world,

where innovation and opportunity are not limited to one side of the economic spectrum, but are available to all as long as adequate instruments and farsighted leadership are at hand.

KEY TERMS AND DEFINITIONS

Information and Communication Technology for Development (ICT4DEV): The universe of internet-related applications that in the different sectors of a Knowledge Society (KS), support boosting the living conditions of people, particularly in EE.

Knowledge Economy (KE): An economy based on knowledge as its principal asset. In a KE, knowledge is the new currency and ICT is a tool to enabling its attainment. Particularly important for emerging economies (EE).

Knowledge Society (KS): A society where tacit and explicit knowledge represent its main backbone. In a KS, local and indigenous knowledge are valued; imported knowledge is adopted whenever it could be adapted to local conditions; and new knowledge can be created to serve societal purposes.

Sustainable Development (SD): The set of economic, social, environmental, and institutional conditions that guarantee a constant or increased flux of benefits for the members of a given society. For societal development to be sustainable, such conditions would have to tend towards equity, fair distribution of benefits, and durability in the use of natural and financial resources.

Sustainable Development Goals (SDG): The new set of SD United Nations goals to be attained by 2030 in order to improve the living conditions worldwide. In the SDG, ICT4DEV is an enabling common denominator supporting tool.

ENDNOTES

¹ This chapter largely draws from the work of Mr. Adithya Raghunathan: *The Economic Advantage of Wireless Infrastructure for Development*. Mr. Adithya Raghunathan was a consultant with the Information and Communication Technologies for Develop-

ment Division (SDS/ICT), IADB, when this paper was written. The author is grateful to Edward Malloy and Jeff Cochrane of USAID, Beatriz Acosta of Corporación Politécnica Nacional (Colombia), and Colin Maclay and Michael Best of the Harvard Berkman Center for Internet and Society who graciously agreed to be interviewed for this report. He also acknowledges the comments of Daniel Aghion of the Wireless Internet Institute. In addition, the author recognizes the dedicated and detailed analysis provided by this paper's reviewers: María Paula Duque Samper, Ministry of Communications, Colombia; Harry Silverstone, EION Wireless; and Guillermo Castillo and Maximilian Spiess, SDS/ICT.

² A declaration was issued during the first phase of meetings, which were held in Geneva, Switzerland on December 10 to 12, 2003.

³ This includes such remote areas as the Andes or the Amazon. See case study on the Amazon Association Project.

⁴ Sixty-three percent of eligible students enrolled in primary school and only 8 percent did so in secondary school. Approximately 1 percent of students finished secondary school and went on to post-secondary education.

Communities of Practice as a Source of Open Innovation

K

Diane-Gabrielle Tremblay
University of Quebec, Canada

INTRODUCTION

In this entry, we first define this new form of learning and knowledge management that is communities of practice. We present the concept as described by the creators of the concept but also comment on the role of these communities in organizational learning or informal learning. We follow with some of the results, centering on the conditions of success and challenges that emerge, as well as limits in the learning and sharing process, which are often underestimated. We highlight some results from a research on communities of practice in Canada, in particular the main conditions and challenges of such new modes of knowledge creation and management, which don't always work automatically. We compare these results to other recent research. Research clearly confirms that participants' commitment and motivation in the project, dynamism and continuity of leadership, organizational support and recognition of employees' involvement are the key elements in a community of practice, and they can contribute to open innovation.

COMMUNITIES OF PRACTICE

The term 'communities of practice' was first used by Brown and Duguid (1991), by Lave and Wenger (1991), and finally by Wenger (1998; Wenger et al., 2002, 2000). It refers to the idea of sharing information and knowledge within a small group, as well as to the value of informal learning for a group and an organization. As is usually the case today, we consider people use technologies (com-

puter, cell phone, ipad, etc.) to exchange with each other, but also to keep track of some information and knowledge the group wants to stock. Wenger et al. (2002) describe a community of practice as a group of participants who:

Don't necessarily work together every day, but they meet because they find value in their interactions. As they spend time together, they typically share information, insight, and advice. They help each other solve problems. They discuss their situations, their aspirations, and their needs. They ponder common issues, explore ideas, and act as sounding boards. They may create tools, standards, generic designs, manuals, and other documents – or they simply develop a tacit understanding that they share. However they accumulate knowledge, they become informally bound by the value that they find in learning together. This value is not merely instrumental for their work. It also accrues in the personal satisfaction of knowing colleagues who understand each other's perspectives and of belonging to an interesting group of people. Over time, they develop a unique perspective on their topic as well as a body of common knowledge, practices, and approaches. They also develop personal relationships and established ways of interacting. They may even develop a common sense of identity. They become a community of practice. (pp. 4-5)

In the 90s, observers mainly studied informal communities that were created spontaneously in a workplace. However, over the years, there has been increasing interest in creating and cultivating such communities in workplaces (Swan et al.,

DOI: 10.4018/978-1-5225-2255-3.ch435

2002; Wenger et al., 2002). Also, more recently, there has been more and more interest in seeing companies and organizations in general as a group of communities of practice and more and more interest in the leadership and empowerment dimension (Cordery et al., 2015), as well as on the impact on innovation (Müller & Ibert, 2015). Many of these communities are teleworking communities or distributed communities (Friberger & Falkman, 2013), often active in an agile and lean environment (Paasivaara & Lassenius, 2014) that use information and communication technologies, and this was the case in the communities we studied.

The following definitions help us to better understand what this concept actually means (Mitchell, 2002):

- Communities of practice are people who share a concern, a set of problems or a passion about a topic, and deepen their knowl-

edge and expertise in this area by interacting on an ongoing basis

- A group whose members regularly engage in sharing and learning, based on their common interests

Wenger et al. (2002) as well as Mitchell (2002), among others, indicate that communities of practice take on various forms, and Table 1 highlights the differences that exist between types of communities. In the cases we studied, communities were of the structured distributed type, most of them being formally supported by one organization, a few being inter-organizational, but all having to do with their work activity and not personal interests, as is more often the case in the informal type of community. Over the years, inter-organizational or inter-cluster interactions (Cusien & Loubaresse, 2015) have become more important, and there is as much interest in these types of communities as in those organized within a single firm, while

Table 1. various forms of communities of practice

Aspects	Informal	Supported	Structured
Objective	Provide a discussion forum for people with affinity of interest or needs within their practice	Build knowledge and capability for a given business or competency area	Provide a cross-functional platform for members who have common objectives and goals
Affiliation	Self-joining or peer invited	Self-joining, member invited or manager suggestion	Selection criteria outlined Invited by sponsors or members
Sponsorship	No organizational sponsor	One or more managers as sponsors	Business unit or senior management sponsorship
Mandate	Jointly defined by members	Jointly defined by members and sponsor(s)	Defined by sponsor(s) with endorsement of members
Organizational support	General endorsement of communities of practice Provision of standard collaborative tools	Discretionary managerial support in terms of resources and participation Supplemented array of tools and facilitation support	Fully-fledged organizational support on the same basis as organizational segments Budget allocation as part of business plans
Infrastructure	Most likely meets face-to-face; primary contact Has a means of communication for secondary contact	Uses collaborative tools Meets face-to-face on a regular basis	Uses sophisticated technological infrastructure to support collaboration and store knowledge objects generated in the community Highly enabled by technology
Visibility	So natural that it may go unnoticed	Visible to colleagues affected by the community's contribution to practice	Highly visible to the organization through targeted communication efforts that are stewarded by sponsors.

Source: Davel and Tremblay (2011)

the boundaries of the firm becomes an important issue (Contu, 2014).

Much existing literature centers on face to face communities (Gherardi & Nicolini, 2000), but many communities actually function in a context of distance or telework (Hildreth & Wright., 2000). This brings us to the issue of virtual communities of practice, which are more and more common in a global environment. In our view, this virtual dimension is an important aspect of communities of practice theory, especially in the global context.

At first, authors mainly studied informal communities that were created spontaneously in a workplace. However, over the years, there has been increasing interest in the creation of such communities in workplaces (Wenger & Snyder, 2000), and even in the creation of teleworking communities that use information and communication technologies. Task interdependence appears crucial (Cordery et al., 2015).

The advantages of communities are said to be the following: informal diffusion of relevant knowledge, exchange of knowledge between peers and, as a result, improvement of innovation and productivity.

Much of the literature centers on face to face communities, while many function in a context of distance or telework, which brings us to talk of virtual communities of practice, which is what we studied in our project, and is more and more common in a global environment. In our view, this virtual, or rather, distance dimension is an important dimension, especially in the global context, and it requires more detailed analysis, which is why this research was done.

Also, much of the literature does not take into account the temporal dimension, but it does appears essential in analyzing organizations, since mutual engagement appears to be crucial (Gau, 2014) and this engagement tends to evolve over time. The most detailed model of the evolution of communities of practice was presented by Wenger et al. (2002), but in our view it again presents a very normative portrait of communities of practice, from which reality often departs.

Wenger et al. (2002) and Bourhis and Tremblay (2004) define five stages. At the beginning, the community is an informal network, a potential community. It then unites itself and acquires maturity, and then momentum, and becomes productive (Mitchell, 2002) until at some point, an event makes it essential for the community to change or renew itself. Again, this seems a little normative in comparison to the real life of communities, and we wanted to better understand the variables which influence the life of communities.

Let us now turn to conditions of success of these communities. First, group work always requires a number of conditions and the communities of practitioners (CoPs) are not an exception to this rule. On the contrary, these conditions are certainly even more important in the CoP context, since participants must in principle share tacit knowledge, collectively build up knowledge, and solve production or service problems. In this context, in our view, the social relations between actors and demographic characteristics cannot be neglected, although they tend to be in the literature on communities of practice. We therefore turned to the literature on collaborative learning to dig into the reality more deeply and put forward new questions to the participants of the communities.

One of the main conditions mentioned in the literature on collaboration and collaborative learning concerns the engagement and commitment of participants to the task or the community, as well as the interest and motivation of individuals to work together as a group (Gau, 2014). In the Community of practice (CoP) literature, some authors refer to a “joint enterprise” to describe the mission or common objective that participants give to a CoP. However, few authors have determined how to foster this commitment, which appears to be taken for granted regardless of the context and the social relations of work, whereas in reality this is not the case. Second, many authors emphasize the importance of having a shared set of resources or what could be referred to as “common baggage,” or common language, in order to facilitate exchanges and avoid misunderstandings

and conflicts. We now turn to some results from our study of CoPs in order to support some of the elements put forward here.

RESULTS

The results are derived from an action research on a dozen communities of practitioners (CoPs) conducted under the aegis of the *Centre francophone d'informatisation des organisations* (CEFRIO). In fact, seven CoPs have actively participated in the research. One hundred and eighty (180) participants answered questionnaires on starting up a CoP and slightly less than 100 participants answered evaluation questionnaires six months later. In addition, focus groups and recordings of critical incidents in each of the communities were also conducted so as to better understand the dynamics of each of the CoPs. We will focus on the aspects related to learning and training, paying particular attention to the conditions and challenges that emerge from our results.

Let us first present a few demographic characteristics of our respondents. The majority of respondents, that is 60% (105 out of 173 respondents to this question), were aged from 35 to 49. However, there is a good differentiation in ages, which permits some statistical analyses, as we will see later. There were 61% women against 39% men (105 women, 68 men out of 173 respondents).

Attainment of Objectives

Although the objectives of the communities of practitioners studied differed (Tremblay, 2008), they were mainly aimed at learning through exchange and collaboration. From this perspective, it is interesting to note how the objectives have evolved over time. When the communities were starting up, the objectives identified by the participants were usually related to exchange and sharing of information and knowledge, better utilization of delocalized resources, as well as the creation of a collective memory - objectives which actually

pertain to learning through interaction, something common to most CoPs (Lee et al., 2015).

It must first be stressed that in our research, the majority of respondents to this question had mixed feelings about the success and usefulness of the community, even though they think that it has had a positive impact on the work climate. Thus, although the participants do not appear to be enthusiastic, collaboration within the CoPs seems to be rather positive (Bourhis & Tremblay, 2004), and networking and co-learning are indeed an important objective of CoPs (Jimenez-Zarco et al., 2015).

However, after a few months of work in a virtual CoP, the achievement of objectives seemed to be uneven. In fact, although certain CoPs felt that they had achieved their objectives (Tremblay, 2008, 2004a), this was not so true of other CoPs. Perhaps it was still too soon to assess the achievement of objectives since, unlike project teams or groups, CoPs are not supposed to have a specific schedule and they have to learn new operating modes in a short time.

Concerning the partial achievement of the objectives of CoPs, there are various possible reasons for this, including the frequent change of CoP leader, the loss of interest on the part of management or participants, or the lack of time for participation. However, it must be stressed that developing learning and experimenting with a new problem-solving approach, which were not always among the objectives considered to be the most important at first, seemed to have been relatively well achieved by a number of CoPs and these forms of learning are greatly appreciated by the participants. There appear to be criteria and conditions for CoPs to function and clearly, this type of arrangement cannot be transferred anywhere or globalized without taking into account these considerations.

It must be stressed that all of the CoPs operated with a knowledge-sharing telesoftware. The participants were either not very familiar with the software or had to more or less master it in a few months, depending on how easy or difficult it was

for them to use this software and the time—which is generally limited—that they had. The use of software such as Knowledge Forum or Lotus Notes, which was different in each case, allowed CoP participants to exchange messages. These were then grouped together on a space and could be reviewed and re-organized according to the themes discussed in the exchanges. In principle, this is how virtual (i.e., teleworking) communities must jointly develop knowledge.

We analyzed the data on success or attainment of objectives according to various demographic variables, but only two (gender and age) came out significantly in some of the analyses. For various reasons, often lack of variance in the respondents, the other variables tested did not show up as significant: level of schooling, professional category, language but could be the object of other research in the future. There were 178 respondents in the first phase of the research (1st questionnaire) and 106 in the second phase, six months later, which essentially addressed issues of impact and results. The success of the CoP was evaluated in different ways, amongst which the attainment of the strategic and operational objectives of the CoP.

Sources of Satisfaction

Satisfaction or dissatisfaction with the CoP are an important issue, as they impact on engagement of participants (Gau, 2014). In general, participants appreciated the pertinence of the topics addressed in the exchanges in relation to their work, the collaboration between members, the solving of work problems, the establishment of consensus, group work, and the development of new skills. They were slightly more critical of the quality of the exchanges, which was viewed differently by the various CoPs. It must, however, be noted that younger participants seemed to appreciate all these aspects more than participants aged 50 or over. More in-depth analysis is needed to determine whether age alone explains this finding or whether other variables might be more important in the explanation, such as the specific local context,

the topic, the leadership (Paasivaara & Lassenius, 2014) or the level of engagement (Gau, 2014).

Participants were also asked to assess different aspects of their experience. It was clear that the most interesting aspect for participants was learning from other people as well as exchanging and sharing information and knowledge in a supportive environment and this is found regularly over the years as a main source of interest and engagement (Paasivaara & Lassenius, 2014; Gau, 2014). Nevertheless, it is interesting to note that the majority of our participants thought that they had learned more from others than had contributed to the exchanges themselves. It thus seems that there was a deficit in active participation by CoP members, since many of them remained somewhat on the periphery of the community's central core, in what is referred to as "peripheral participation." (more detail in Tremblay, 2004, 2005a, 2008).

It must be noted that women's involvement in the project was often slightly higher than that of men, at least according to their own evaluation. More research needs to be done however on this issue of involvement and participation, according to gender, since other elements of context (organizational culture, passionate leadership, decision making process, the interest in the topic, etc.; cf. Paasivaara & Lassenius, 2014) might also explain the stronger involvement of some participants.

Sources of Dissatisfaction

The main sources of dissatisfaction identified by our participants relate to the lack of recognition of participation by the employer, sometimes also the lack of peer recognition, and in particular the too often limited time (given the objectives), spent on the community's activities. In fact, the majority of participants were not released from other tasks to participate in the CoP and this activity therefore ate up their working time (Tremblay, 2004). However, the most satisfied CoP in this regard is made up of a group of some 20 female health professionals, whose CoP was not supported by their employer but by a professional association,

and thus the participants used their personal time to participate (Tremblay, 2004). Once again, motivation and engagement to the project emerged as the key variables in the success of this CoP, as other authors have also shown (Gau, 2014). Participants were willing to put personal time in a project because the knowledge acquired and the achievements seemed to be worth their while.

In contrast, in other cases, the achievements were apparently too minor or not sufficiently visible or satisfactory. This negative view was confirmed by the fact that the majority did not think that the CoP activity would be recognized in their performance evaluation, career progression, and skills assessment. However, it seemed that participants were generally more optimistic about the recognition of their learning by colleagues, although this did not yield concrete results in career terms.

It must be noted that most of the participants in the CoPs we studied did not know each other well beforehand, but were designated to participate in these CoPs. Therefore not all of them were volunteers and as trust-building is important, this may have been an issue here. Moreover, one CoP in which most participants did not know each other at all – composed of the female health professionals – was the most successful case in our view, which means that other factors (mutual engagement in this case, *cf.* Gau, 2014) can compensate for prior acquaintance. Nevertheless, the latter is deemed to be important by many authors, as it is considered to be a source of trust and greater collaboration between participants. Indeed, it was found that although prior acquaintance can make it easier to collaborate in certain CoPs, it is not a sufficient condition for them to achieve their objectives. Thus, although being in the habit of collaborating can result in trust, which is generally considered to be essential to collaboration and learning, it is evident that participants need additional motivation to move the CoP forward and achieve its objectives. Moreover, it should be noted that women spent twice as long as men on

CoP activities, on average, one hour versus half an hour for men.

These observations contribute to the existing literature on communities of practice, since it nuances the importance of prior acquaintance and organizational support, often considered as determinant characteristics of the success of communities of practice. Our research tends to highlight the importance of commitment, personal and mutual engagement (as in Gau, 2014) and interest co-learning (Jimenez-Zarco et al., 2015). It may also be that the most successful groups had less difficulty working from a distance or teleworking (Paasivaara & Lassenius, 2014; Tremblay, 2003, 2002).

Our research had some limits of course, but recent research seems to center on the same questions, which should be explored further: Which groups are more motivated by this form of co-learning (Jimenez-Zarco et al., 2015)? How can one develop trust and passion for the topic (Paasivaara & Lassenius, 2014) in order for people to be willing to share knowledge? To what extent is a passionate leadership essential for success (Paasivaara & Lassenius, 2014)?

CONCLUSION

To conclude, a number of factors related to the conditions and challenges associated with CoPs are summarized in order to identify those which would help promote the wider use of these co-learning practices (Jimenez-Zarco et al., 2015).

The participants in our research mentioned that participants' engagement was considered to be a crucial factor in the success of CoPs, as was also observed by Gau (2012). In fact, the most successful CoP was one in which the participants' engagement was indeed important (Tremblay, 2004). However, other factors can play a role in explaining the more mixed success of other cases: for example, the frequent change of leaders and the lack of dynamic leadership (Paasivaara and

Lassenius, 2014), the degree of decentralization of the firm (Dumitru and Enachescu, 2015). These various factors must be taken into account when developing co-learning through communities of practitioners. One of the communities which functioned the best was headed by a female health professional who had been hired specifically for this task, and therefore invested the necessary time in the project (Tremblay, 2005a, 2005b) and provided dynamic leadership (Paasivaara & Lassenius, 2014).

It was also shown that the support offered to participants by the organization can be a factor of success. However, our results indicated that most of the participants would not necessarily have wanted more resources or training (in conflict management, communication or problem solving) even though few had received the training. Therefore, our findings suggest that training and support resources are not as important in the success of CoPs as is indicated in the literature, while leadership and engagement appear crucial (Paasivaara & Lassenius, 2014; Gau, 2014). The engagement of participants appears to sometimes compensate for the lack of organizational support. Participants indicated that their organization's interest in the CoP had not increased over time and this also seems to be one of the challenges associated with the medium- and long-term viability of CoPs. Again, one of the most successful cases was one composed entirely of female health professionals which was outside of the employer organizations and therefore this indicates that organizational support is not necessarily the most important source of success, personal engagement appearing to be as determinant (Gau, 2014; Tremblay, 2008).

In any case, although relatively new, this CoP formula offers interesting prospects for learning, but we can see that it cannot be generalized without considering various dimensions including leadership and engagement, and various characteristics of the community need to be taken into account,

since they may have an impact on success and attainment of objectives.

FUTURE RESEARCH DIRECTIONS

Research clearly needs to be pursued on issues such as leadership, engagement, goal-setting, decision-making processes, as well as the conditions and factors of success. Also the differences between formal and informal CoPs should be analyzed in more detail, as there has been relatively little comparative work on this (Tebogo et al., 2015). There has been work on informal CoPs in but it has been strongly concentrated in the field of education; there has been much less work in management on the issues and challenges that CoPs pose in terms of leadership and engagement, much of the literature being of a normative nature. This is why we wanted to contribute by doing some empirical research to test to what extent learning and sharing was actually occurring and to try to identify the factors that make it happen. Over the years, various authors have contributed to the literature (Paasivaara & Lassenius, 2014; Gau, 2014), but research needs to be pursued on these two crucial factors that are leadership and engagement. In our view, there also needs to be more research on inter-cluster or inter-organizational interactions, to go beyond the boundaries of the firm.

KEY TERMS AND DEFINITIONS

Communities of Practice: The term was first used by Brown and Duguid (1991) and by Lave and Wenger (1991) and then by Wenger et al. (2002). It refers to the idea of sharing information and knowledge within a small group, as well as to the value of informal learning for a group and an organization.

Telework: Work from a distance of the main office, either at home or in telework centers, generally using technologies.

INTRODUCTION

The importance of cultural values to management practices in Africa has become increasingly obvious in recent years as many expectations of African organizations and institutions created and managed along lines of Western textbooks and models have not achieved the expected results of sustainable economic development and growth. In Africa, we have very limited knowledge about its cultural values and the consequences it poses for African intellectuals and management practice in African organizations.

While the African intellectuals are very knowledgeable about accepted theories and models of the Western world, knowledge about cultural values of their society is limited. The African intellectuals are not equipped enough to understand the obligations imposed on them by Western cultural values in which they have been socialized and the traditional environment in which they were born and raised, thus, making their ability to contribute something original to the development of their society limited.

Because of failure of the Westernized African managers to identify and take advantage of the 'growth-positive' cultural values of their society for effective management practice that the relevancy of western management theories and models utilized in training managers in Universities and business schools to managing organizations in Sub-Saharan Africa comes into question.

Africans have ways of exercising power and authority at the workplace, ways of motivating

and rewarding people to make them work harder. Neither the institutions nor the political structures put in place by the colonizers and the so-called African intellectuals to Westernized Africa have respected these indigenous knowledge structures, but much of them have survived in the traditions and cultural values of the African people. However, unlike in Europe and most part of Asia, the attempted modernization or Westernization after independence has completely neglected the native cultural traditions and tried to transfer or transplant ready-made western management theories and models to traditional African soil. The results of these transformations, in most cases, have been disappointing.

The objective of this paper is to draw attention to the relevance of cultural values in management philosophy with the purpose of contributing to a culturally viable and appropriate theories and practice of management in Sub-Saharan Africa. Management practice in Africa requires identification of "growth-positive" and "growth-negative" culture-based factors.

BACKGROUND

Culture Stabilization Patterns

The model of Figure 1, taken from Iguisi and Hofstede (1993), indicates how we assume culture patterns in a country to stabilize themselves through feedback loops, but also to change under the influence of outside forces.

Figure 1. The stabilization of culture patterns

Source: Igusi and Hofstede (1993, p. 3)

The system of this model in Figure 1 implies that one cannot understand one element—such as, management practice philosophy within the local environment—without its societal and cultural value context.

In the center is a system of societal norms, consisting of the value systems shared by major groups of the population. Their origins are in a variety of ecological factors (in the sense of factors affecting the physical environment). The societal norms have led to the development and pattern maintenance of institutions in society with a particular philosophy, structure and way of functioning. These include the family, education systems, politics, and legislation. These institutions, once they have become facts, reinforce the societal norms and the ecological conditions that led to them. According to Hofstede, in a relatively closed society, such a system will hardly change

at all. Institutions may change, but this does not necessarily affect the societal norms; and when these remain unchanged, the persistence influence of a majority value system patiently smooths the new institutions until their structure and functioning is again adapted to the societal norms. Change comes mainly from the outside, through forces of nature (change of climate, silting up of harbors) or forces of man (trade, colonization, scientific discovery) (Hofstede, 1980). The arrow of outside influences is deliberately directed at the origins, not at the societal norms themselves. It is believed that norms change rarely by direct adoption of outside values, but rather through a shift in ecological conditions: technological, economical, and hygienic. In general, the norm shift will be gradual unless the outside influences are particularly violent (Hofstede, 1980a).

The Place of Cultural Values in African Philosophy Discourse

The value of a thing, be it an object or a belief, is normally defined as its worth. Just as an object is seen to be of a high value that is treasured, our beliefs about what is right or wrong that are worth being held are equally treasured. According to Idang (2015) a value can be seen as some point of view or conviction which we can live with, live by and can even die for. This is why it seems that values actually permeate every aspect of human life. For instance, we can rightly speak of religious, political, social, aesthetic, moral, cultural and even personal values. We have observed elsewhere that there are many types and classifications of values. As people differ in their conception of reality, then the values of one individual may be different from those of another. Life seems to force people to make choices, or to rate things as better or worse as well as formulate some scale or standard of values. Depending on the way we perceive things we can praise and blame, declare actions right or wrong or even declare the scene or objects before us as either beautiful or ugly. Each person, as we could see, has some sense of values and there is no society without some value system (Idang, 2009, p. 4).

Whether we are aware of it or not, the society we live in has ways of daily forcing its values on us about what is good, right and acceptable. We go on in our daily lives trying to conform to acceptable ways of behaviour and conduct. Persons who do not conform to their immediate society's values are somehow called to order by the members of that society. If a man, for instance, did not think it wise to make honesty a personal value, and it is widely held by his immediate society that truth telling is a non-negotiable virtue, it would not be long before such an individual gets into trouble with other members of his society. This shows that values occupy a central place in a people's culture. It forms the major bulwark that sustains a people's culture, making it more down-to-earth and real. Elsewhere, we have seen African culture

as "all the material and spiritual values of the African people in the course of history and characterising the historical stage attained by Africa in her developments" (Idang, 2009, p. 142). This simply means that there is a peculiar way of life, approach to issues, values and world views that are typically African.

Based on cultural considerations, some forms of behaviour, actions and conduct are approved while others are widely disapproved of. To show the extent of disapproval that followed the violation of values that should otherwise be held sacred, the penalty was sometimes very shameful, sometimes extreme. Antia (2005) says that "what a people hold to be true, right or proper with regard to those things explains much of the cultural traits by which they become identified". What Antia calls "traits" here can as well be called values; and Etuk (2002) writes that "no group of people can survive without a set of values which holds them together and guarantees their continued existence".

Values, whether "growth-positive" or "growth-negative", occupies a very wide area in the discipline of philosophy. To show the fundamental importance of values, it is regarded as a core area in philosophy, together with knowledge and reality. When we are dealing with actions that a people see as good or bad, right or wrong, praiseworthy or blame-worthy, we are dealing with the aspect of value theory that rightly falls under ethics or moral philosophy. Having seen the centrality of values to African culture and any culture for that matter, it can be stated that the "growth-positive" and "growth-negative" values of culture are what give it uniqueness and identity. Let us now look at African philosophy discourse.

African Philosophy Discourse

Anthropologist and sociologists have come across multi-farious patterns of family, kinship, and political, religious, economic and technological organisations. The variety extends to morals, beliefs, art and languages. It is now generally accepted that societies have divergent ways of expressing their

thoughts about themselves and their world and of organizing their activities. The non-industrialized societies with the most primitive technology have in their explanations of natural processes and the supernatural, organised their lives on these assumptions, which may seem outlandish to the industrialized or industrializing men who have their own way of conceptualising reality by separating the natural from the supernatural.

Several African writers such as Mbiti (1969), Abimbola (1976) Oruka (1990, 1998), and Gbadegesin (1991, 1998) have all attempted to elaborate on some aspects of African philosophy though they have not clearly stated this attempt. Onwuejeogwu (1978, 1997), extensive empirical fieldwork in the study of African divination and social action, demonstrates that African traditional philosophy is based on the relationship linking the past, present and future. Accordingly, this conception is expressed in an African genealogical structure that models the collective existence and actions of contemporaries (the living), in terms of predecessors (ancestors), and successors (the unborn). In this system of beliefs, grandfathers under certain metaphysical conditions are expected to re-incarnate in their grandchildren: thus the past is linked with the future through the present (Onwuejeogwu, 1978).

In the African traditions, it is the community that defines the person as a person. "Ubuntu" as a translation of the Xhosa expression "Umuntu ngumuntu ngabantu" means the person is a person through other persons, and this expresses a typical African conception of a person. Mbigi (1995) defined "Ubuntu" as the sense of solidarity or brotherhood, which arises among people within marginalized or disadvantaged groups. They acknowledged that it is not culturally specific to African people or communities but may be manifest elsewhere and they restate the collective shared experience of African peoples. Jackson (2005) and Mangaliso (2001) provide literal translation of Ubuntu as "I am who I am through others". Karsten and Illa (2005) see Ubuntu as humaneness and pervasive spirit of caring and

community, harmony and hospitality, respect and responsiveness that individuals and groups display for one another. Ubuntu provides a strong philosophical base for the community concept of management (Khoza, 1994). Mbigi (1997) has listed the following relevant principles of Ubuntu as the spirit of unconditional African collective contribution, solidarity, acceptance, dignity, stewardship, compassion and care, hospitality and legitimacy. Ubuntu is an African worldview that is rooted and anchored in people's daily lives.

On the basis of an extensive review of literature in African studies, Ahiauzu (1986) has shown that there exists a great deal of similarity in the general ways of life of black Africans. For example, he provided empirical evidence that there clearly exists an African thought-system, quite different from that of other societies. According to Ahiauzu, African thought system draws largely from proverbial social thought, while theoretical thinking in traditional African society is mystical based mainly on the actions of gods, ancestral spirits and other kinds of spirits (Ahiauzu, 1986). Numerous studies of African cosmologies have highlighted the influences of gods and different kinds of spirits on the life of the African (Horton, 1962, 1954; Uchendu, 1965; Barber, 1981; Lienhardt, 1961; Middleton, 1960; Fortes, 1959; Biko, 1984, 1998; Wiredu, 1995; Prinsloo, 1998). If it is accepted, therefore, that the natives of Africa can be identified by certain common characteristics in their ways of life, as suggested by a host of scholars of African studies (Blyden, 1908; Donohugh, 1935; Busia, 1967; Sithole, 1959; Wilson, 1936), particularly an identifiable unique system of social thought (Otite, 1978; Adesanya, 1958; Horton, 1967; Maquet, 1972; Ahiauzu, 1986; Kopyoff, 1997; Fanon, 1997), then there might exist an indigenous African Management philosophy.

African Management Philosophy

In the last few years a body of literature has arisen in response to Africa's relegation to the margins of global considerations of management practice.

This field of study has become known as African management philosophy defined as:

The practical way of thinking about how to effectively run organisations be they in the public or private sectors on the basis of African ideas and in terms of how social and economic life is actually experienced in the region. Such thinking must be necessarily interwoven with the daily existence and experience in Africa and its contextual reality. (Edoho, 2001, p. 74)

Proponents of African management philosophy argue that Africa's effort to engineer authentic development will continue to be unsuccessful until indigenous management systems are established and institutionalised (Anyansi-Archibong, 2001; nken & Jones, 1997; Edoho 2001; Kamoche, 2000; Mangaliso, 2001; Mbigi, 1997, 2005; Ngambi, 2004). The call for indigenous approaches to management falls within the broader call for an African Renaissance that seeks to reclaim the identity of Africans (Makgoba, 1999; Mbeki, 1998; Mudimbe, 1988; Nzelibe, 1986). It is also consistent with post-colonial theory, which calls for the colonised to reclaim a culture of their own, a history of their own, aesthetics of their own, all based on an essence of their own, free from and independent of the images of the 'Other' (Said, 2002; Prasad, 1997; Ghandi, 1998; Spivak, 1990).

If Africa was better managed in the past, what went wrong and how can it be reclaimed? Colonialism is identified as the culprit for the often corrupt and ineffective management of organisations in many African countries. The underlying belief is that if indigenous African management can be reclaimed and re-institutionalised in Africa, there would be a positive effect on resolving significant problems of poverty, economic stagnation and development.

Proponents of African management philosophy look to the history of Africa and the presence of indigenous knowledge systems that resulted in effective management during the pre-colonial era (Iguisi 2012, Edoho, 2001; Kiggundu, 1993;

Ngambi, 2004; Nzelibe, 1986). Describing management systems during the pre-colonial period remains problematic because of the scarcity of written documentation of such systems. However, this has not prevented scholars from offering descriptions of African management systems. In offering such descriptions, scholars draw heavily from the literature in African studies and writings of African historians (e.g.; Mazrui, 1998; Iguisi & Deva 2014).

How are the basic dimensions of African management and leadership described in these writings? While writers (Ahiauzu, 1997; Mutabazi, 2002; Mbigi, 2005) often point to the vast diversity in Africa, the focus is on offering generalised descriptions of African management. Whereas Western management thought is said to advocate Eurocentricism and individualism, African management thought is said to emphasize traditionalism, communalism, cooperative teamwork, and mythology. Traditionalism has to do with the adherence to accepted customs, beliefs and practices that determine accepted behaviour, morality and characteristics of individuals in African society.

African management philosophy is also said to be characterised by a strong belief in the individual's relation to nature and supernatural beings, and connections between the individual and ancestors (Mbigi, 1997, 2005). Nzelibe (1986, p.12) argues that the continuity from the material to the spiritual is the universal basis of African management philosophy.

FUTURE RESEARCH DIRECTIONS

Consequences for Organisations in Africa

One remarkable scientific comment made by Ahiauzu (1985b) in his empirical study of African workers in Nigeria and a host of other African countries, was that when ordinary Africans are observed in traditional workplaces, such as vil-

lage farms, local communal work organisations, and self-employment where African indigenous managerial and work organisational practices are largely adopted, the Africans are normally seen to be relatively relaxed and hardworking. But when they come to town and become employed in government public service organisations, industrial or other modern work organisations, their attitudes to work and general work behaviour falls far below expectation.

Adopting the foregoing view as a frame of reference, and pondering on the behaviour and general reactions of the Africans in modern organisations, one important question comes to mind. The question is: is it logical for management scholars and social scientists, to attempt to obtain a genuine understanding and explanation of the work behaviour of Africans in modern organisations, by adopting constructs and theoretical frameworks developed by social scientists in the Western world? Mitchell (1967) has made a statement that assists us in addressing the question. The author argues that social scientists:

Are prone to think their work is the outcome of a play of free intelligence over logically formulated problems. They may acknowledge that their ideas have been influenced by their reading and the teaching which they were wise enough to choose, but they seldom realize that their free intelligence has been moulded by the circumstances in which they have grown up; that their minds are social products; that they cannot in any serious sense transcend their environment. (pp. 36-37)

Mitchell's argument suggests that Western management and theories are the products of the minds of persons, which have unconsciously been moulded by the circumstances in which those theorists have grown up.

There is the belief in African philosophy that all the provinces of meaning of an African in his everyday life are interrelated. Because of the strong relationship between the work and non-work realities of Africans, and because of

inherent inability to achieve a complete leap of consciousness when shifting from non-work to work realities, the major structural features that characterise the self-perception and relational processes of Africans in their non-work world, cannot be ignored while developing management and organisational behaviour theories to be adopted in understanding and explaining their behaviours in modern organisations.

The challenge in African management discourse is to reflect on the different cultural and philosophical discourses, management theories and research methodologies to present an African methodological perspective upon which to develop appropriate theoretical constructs and frameworks to be used in understanding and explaining the values and behaviours of African managers in modern organisations, bearing in mind the nature of the elements that structure their work and non-work worlds.

CONCLUSION

It is truly disappointing to find that, despite available evidences (see Frank, Hofstede, & Bond, 1991; Hofstede, 2005, 2011; Boon, 2005; Iguisi, 1994, 1998, 2014), towards the role of cultural values in management for African scholars, leaders, managers, and international development agencies that have been prescribing Western formula for African development to have not recognized that culture does have greater part to play in their consideration for management and economic development issues in Africa.

This paper has discussed the issues of the role of culture in management and a number of issues in Western management theories and assumptions that are culturally conditioned. Effectiveness and appropriateness within a given culture, and judged according to the values of the culture, call for management theories and assumptions reflective of the local culture. The point we are making here comes out more clearly if one draws from both oral tradition and written historical records.

Before the advent of colonial administration, the old African villages and towns had effective public administrative mechanism, which the village and town heads, chiefs and kings administered. The use of anthropological concepts in this context will help in the development of appropriate organizational behavior and effective management practice congruous with the local cultures and traditions.

African scholars and practicing managers aware of the possibilities of their cultural values for modern management practice can hold their head erect and put their best foot forward at any feat they may attempt. They need not assume the role of black-Europeans or Americans to be good scholars or managers; there is enough strength in African cultures and traditions to enable them perform wonders in any modern organization. African scholars, managers, and practitioners' conscious of their cultural values, more importantly, the 'growth-positive' cultural value factors in their societies can perform best in modern organizations.
